ABSTRACT BASE CLASS FOR SAGE OBJECTS

```
Abstract base class for Sage objects
class sage.structure.sage_object.SageObject
     Bases: object
     x.__init__(...) initializes x; see help(type(x)) for signature
     category()
     db (name, compress=True)
          Dumps self into the Sage database. Use db(name) by itself to reload.
          The database directory is $HOME/.sage/db
     dump (filename, compress=True)
          Same as self.save(filename, compress)
     dumps (compress=True)
          Dump self to a string s, which can later be reconstituted as self using loads (s).
          There is an optional boolean argument compress which defaults to True.
          EXAMPLES:
          sage: O=SageObject(); O.dumps()
          'x\x9ck'J.NLO\xd5+.)*M.)-\x02\xb2\x80\xdc\xf8\xfc\xa4\xac\xd4\xe4\x12\xae' \xdb\x1f\xc2,d\xc
          sage: O.dumps(compress=False)
          '\x80\x02csage.structure.sage_object\nSageObject\nq\x01)\x81q\x02.'
     rename (x=None)
          Change self so it prints as x, where x is a string.
          Note: This is only supported for Python classes that derive from SageObject.
```

```
sage: x = PolynomialRing(QQ, 'x', sparse=True).gen()
sage: g = x^3 + x - 5
sage: g
x^3 + x - 5
sage: g.rename('a polynomial')
sage: g
a polynomial
```

```
sage: g + x
x^3 + 2*x - 5
sage: h = g^100
sage: str(h)[:20]
'x^300 + 100*x^298 - '
sage: h.rename('x^300 + ...')
sage: h
x^300 + ...
```

Real numbers are not Python classes, so rename is not supported:

```
sage: a = 3.14
sage: type(a)
<type 'sage.rings.real_mpfr.RealLiteral'>
sage: a.rename('pi')
Traceback (most recent call last):
...
NotImplementedError: object does not support renaming: 3.1400000000000
```

Note: The reason C-extension types are not supported by default is if they were then every single one would have to carry around an extra attribute, which would be slower and waste a lot of memory.

To support them for a specific class, add a cdef public __custom_name attribute.

reset_name()

Remove the custrom name of an object.

EXAMPLES:

```
sage: P. <x> = QQ[]
sage: P
Univariate Polynomial Ring in x over Rational Field
sage: P.rename('A polynomial ring')
sage: P
A polynomial ring
sage: P.reset_name()
sage: P
Univariate Polynomial Ring in x over Rational Field
```

save (filename=None, compress=True)

Save self to the given filename.

EXAMPLES:

```
sage: f = x^3 + 5
sage: f.save(os.path.join(SAGE_TMP, 'file'))
sage: load(os.path.join(SAGE_TMP, 'file.sobj'))
x^3 + 5
```

version()

The version of Sage.

Call this to save the version of Sage in this object. If you then save and load this object it will know in what version of Sage it was created.

This only works on Python classes that derive from SageObject.

```
sage.structure.sage_object.dumps(obj, compress=True)
Dump obj to a string s. To recover obj, use loads(s).
```

Dump obj to a string s. To recover obj, use 10aas (5)

See Also:

```
dumps()

EXAMPLES:
    sage: a = 2/3
    sage: s = dumps(a)
    sage: print len(s)
    49
    sage: loads(s)
    2/3

sage.structure.sage_object.have_same_parent(self, other)
    EXAMPLES:
    sage: from sage.structure.sage_object import have_same_parent
    sage: have_same_parent(1, 3)
    True
    sage: have_same_parent(1, 1/2)
    False
    sage: have_same_parent(gap(1), gap(1/2))
    True
```

sage.structure.sage_object.load(compress=True, verbose=True, *filename)

Load Sage object from the file with name filename, which will have an .sobj extension added if it doesn't have one. Or, if the input is a filename ending in .py, .pyx, or .sage, load that file into the current running session. Loaded files are not loaded into their own namespace, i.e., this is much more like Python's execfile than Python's import.

Note: There is also a special Sage command (that is not available in Python) called load that you use by typing sage: load filename.sage # not tested

The documentation below is not for that command. The documentation for load is almost identical to that for attach. Type attach? for help on attach.

This function also loads a .sobj file over a network by specifying the full URL. (Setting verbose = False suppresses the loading progress indicator.)

Finally, if you give multiple positional input arguments, then all of those files are loaded, or all of the objects are loaded and a list of the corresponding loaded objects is returned.

EXAMPLE:

```
sage: u = 'http://sage.math.washington.edu/home/was/db/test.sobj'
sage: s = load(u)  # optional - internet
Attempting to load remote file: http://sage.math.washington.edu/home/was/db/test.sobj
Loading: [.]
sage: s  # optional - internet
'hello SAGE'
```

We test loading a file or multiple files or even mixing loading files and objects:

```
sage: t=tmp_filename()+'.py'; open(t,'w').write("print 'hello world'")
sage: load(t)
hello world
sage: load(t,t)
hello world
hello world
sage: t2=tmp_filename(); save(2/3,t2)
```

```
sage: load(t,t,t2)
hello world
hello world
[None, None, 2/3]

sage.structure.sage_object.loads(s, compress=True)
Recover an object x that has been dumped to a string s using s = dumps(x).

See Also:
dumps()

EXAMPLES:
sage: a = matrix(2, [1,2,3,-4/3])
sage: s = dumps(a)
```

If compress is True (the default), it will try to decompress the data with zlib and with bz2 (in turn); if neither succeeds, it will assume the data is actually uncompressed. If compress=False is explicitly specified, then no decompression is attempted.

```
sage: v = [1..10]
sage: loads(dumps(v, compress=False)) == v
True
sage: loads(dumps(v, compress=False), compress=True) == v
True
sage: loads(dumps(v, compress=True), compress=False)
Traceback (most recent call last):
...
UnpicklingError: invalid load key, 'x'.
```

```
sage.structure.sage_object.picklejar(obj, dir=None)
```

Create pickled sobj of obj in dir, with name the absolute value of the hash of the pickle of obj. This is used in conjunction with unpickle_all().

To use this to test the whole Sage library right now, set the environment variable SAGE_PICKLE_JAR, which will make it so dumps will by default call picklejar with the default dir. Once you do that and doctest Sage, you'll find that the SAGE_ROOT/tmp/ contains a bunch of pickled objects along with corresponding txt descriptions of them. Use the unpickle_all() to see if they unpickle later.

INPUTS:

sage: loads(s)
[1 2]
[3 -4/3]

```
•ob j − a pickleable object
```

•dir - a string or None; if None then dir defaults to SAGE_ROOT/tmp/pickle_jar

EXAMPLES:

```
sage: dir = tmp_dir()
sage: sage.structure.sage_object.picklejar(1, dir)
sage: sage.structure.sage_object.picklejar('test', dir)
sage: len(os.listdir(dir))  # Two entries (sobj and txt) for each object
4
```

TESTS:

Test an unaccessible directory:

```
sage: import os
     sage: os.chmod(dir, 0000)
     sage: try:
           uid = os.getuid()
     ... except AttributeError:
            uid = -1
     sage: if uid==0:
             raise OSError ('You must not run the doctests as root, geez!')
     ... else: sage.structure.sage_object.picklejar(1, dir + '/noaccess')
     Traceback (most recent call last):
     OSError: ...
     sage: os.chmod(dir, 0755)
sage.structure.sage_object.register_unpickle_override(module,
                                                                                       callable,
                                                                    call name=None)
     Python pickles include the module and class name of classes. This means that rearranging the Sage source can
     invalidate old pickles. To keep the old pickles working, you can call register_unpickle_override with an old
     module name and class name, and the Python callable (function, class with call method, etc.) to use for
     unpickling. (If this callable is a value in some module, you can specify the module name and class name, for
     the benefit of explain pickle() when called with in current sage=True).)
     EXAMPLES:
     sage: from sage.structure.sage_object import unpickle_override, register_unpickle_override
     sage: unpickle_global('sage.rings.integer', 'Integer')
     <type 'sage.rings.integer.Integer'>
     Now we horribly break the pickling system:
     sage: register_unpickle_override('sage.rings.integer', 'Integer', Rational, call_name=('sage.rings.integer')
     sage: unpickle_global('sage.rings.integer', 'Integer')
     <type 'sage.rings.rational.Rational'>
     and we reach into the internals and put it back:
     sage: del unpickle_override[('sage.rings.integer', 'Integer')]
     sage: unpickle_global('sage.rings.integer', 'Integer')
     <type 'sage.rings.integer.Integer'>
     In many cases, unpickling problems for old pickles can be resolved with a simple call to
     register_unpickle_override, as in the example above and in many of the sage source files. How-
     ever, if the underlying data structure has changed significantly then unpickling may fail and it will be necessary
     to explicitly implement unpickling methods for the associated objects. The python pickle protocol is described
     in detail on the web and, in particular, in the python pickling documentation. For example, the following ex-
     cerpt from this documentation shows that the unpickling of classes is controlled by their __setstate__()
```

Upon unpickling, if the class also defines the method :meth: '__setstate__', it is called with the unpickled state. If there is no :meth: '__setstate__' method, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary. If a class defines both :meth: 'getstate__' and :meth: '__setstate__', the state object needn't be a dictionary and these methods can do what they want.

method.

object.__setstate__(state)

By implementing a __setstate__() method for a class it should be possible to fix any unpickling problems for the class. As an example of what needs to be done, we show how to unpickle a CombinatorialObject

object using a class which also inherits from Element. This exact problem often arises when refactoring old code into the element framework. First we create a pickle to play with:

```
sage: from sage.structure.element import Element
sage: class SourPickle(CombinatorialObject): pass
sage: class SweetPickle(CombinatorialObject, Element): pass
sage: import __main__
sage: __main__.SourPickle=SourPickle
sage: __main__.SweetPickle=SweetPickle # a hack to allow us to pickle command line classes
sage: gherkin = dumps( SourPickle([1,2,3]) )

Using register_unpickle_override() we try to sweeten our pickle, but we are unable to eat it:
sage: from sage.structure.sage_object import register_unpickle_override
sage: register_unpickle_override('__main__','SourPickle',SweetPickle)
sage: loads( gherkin )
Traceback (most recent call last):
...
KeyError: 0
```

The problem is that the SweetPickle has inherited a __setstate__() method from Element which is not compatible with unpickling for CombinatorialObject. We can fix this by explicitly defining a new __setstate__() method:

```
sage: class SweeterPickle(CombinatorialObject, Element):
         def __setstate__(self, state):
              if isinstance(state, dict): # a pickle from CombinatorialObject is just its inst
                  self._set_parent(Tableaux()) # this is a fudge: we need an appropriate pa
                  self.__dict__ = state
              else:
                  self._set_parent(state[0])
. . .
                  self.__dict__ = state[1]
. . .
. . .
sage: __main__.SweeterPickle = SweeterPickle
sage: register_unpickle_override('__main__','SourPickle',SweeterPickle)
sage: loads( gherkin )
[1, 2, 3]
sage: loads(dumps( SweeterPickle([1,2,3]) )) # check that pickles work for SweeterPickle
[1, 2, 3]
```

The state passed to __setstate__() will usually be something like the instance dictionary of the pickled object, however, with some older classes such as CombinatorialObject it will be a tuple. In general, the state can be any python object. Sage provides a special tool, explain_pickle(), which can help in figuring out the contents of an old pickle. Here is a second example.

```
sage: class A(object):
         def __init__(self, value):
             self.original_attribute = value
. . .
         def __repr__(self):
             return 'A(%s)'%self.original_attribute
sage: class B(object):
         def __init__(self, value):
. . .
             self.new_attribute = value
. . .
         def __setstate__(self, state):
             try:
                 self.new_attribute = state['new_attribute']
             except KeyError: # an old pickle
                 self.new_attribute = state['original_attribute']
         def __repr__(self):
. . .
             return 'B(%s)'%self.new_attribute
. . .
```

```
sage: import __main__
sage: __main__.A=A; __main__.B=B # a hack to allow us to pickle command line classes
sage: A(10)
A(10)
sage: loads( dumps(A(10)) )
A(10)
sage: sage.misc.explain_pickle.explain_pickle( dumps(A(10)) )
pg_A = unpickle_global('__main__', 'A')
si = unpickle_newobj(pg_A, ())
pg_make_integer = unpickle_global('sage.rings.integer', 'make_integer')
unpickle_build(si, {'original_attribute':pg_make_integer('a')})
sage: from sage.structure.sage object import register unpickle override
sage: register_unpickle_override('__main__', 'A', B)
sage: loads( dumps(A(10)) )
B(10)
sage: loads( dumps(B(10)) )
B(10)
```

Pickling for python classes and extension classes, such as cython, is different – again this is discussed in the python pickling documentation. For the unpickling of extension classes you need to write a __reduce__() method which typically returns a tuple (f, args,...) such that f(*args) returns (a copy of) the original object. The following code snippet is the __reduce__() method from sage.rings.integer.Integer.

```
def __reduce__(self):
    'Including the documentation properly causes a doc-test failure so we include it as a commer
    #* '''
    #* This is used when pickling integers.
    #*
    #* EXAMPLES::
    # *
    # *
          sage: n = 5
    # *
          sage: t = n.\_reduce\_(); t
    # *
          (<built-in function make_integer>, ('5',))
    #*
         sage: t[0](*t[1])
    # *
          sage: loads(dumps(n)) == n
           True
    #* ///
    # This single line below took me HOURS to figure out.
    # It is the *trick* needed to pickle Cython extension types.
    # The trick is that you must put a pure Python function
    # as the first argument, and that function must return
    # the result of unpickling with the argument in the second
    # tuple as input. All kinds of problems happen
    # if we don't do this.
    return sage.rings.integer.make_integer, (self.str(32),)
```

sage.structure.sage_object.save(obj, filename=None, compress=True, **kwds)

Save obj to the file with name filename, which will have an .sobj extension added if it doesn't have one, or if obj doesn't have its own save () method, like e.g. Python tuples.

For image objects and the like (which have their own save() method), you may have to specify a specific extension, e.g. .png, if you don't want the object to be saved as a Sage object (or likewise, if filename could be interpreted as already having some extension).

Warning: This will *replace* the contents of the file if it already exists.

```
EXAMPLES:
    sage: a = matrix(2, [1,2,3,-5/2])
    sage: objfile = os.path.join(SAGE_TMP, 'test.sobj')
    sage: objfile_short = os.path.join(SAGE_TMP, 'test')
    sage: save(a, objfile)
    sage: load(objfile_short)
     [ 1
              2.1
     [3 - 5/2]
    sage: E = EllipticCurve([-1,0])
    sage: P = plot(E)
    sage: save(P, objfile_short) # saves the plot to "test.sobj"
    sage: save(P, filename=os.path.join(SAGE_TMP, "sage.png"), xmin=-2)
    sage: save(P, os.path.join(SAGE_TMP, "filename.with.some.wrong.ext"))
    Traceback (most recent call last):
    ValueError: allowed file extensions for images are '.eps', '.pdf', '.png', '.ps', '.sobj', '.svg
    sage: print load(objfile)
    Graphics object consisting of 2 graphics primitives
    sage: save("A python string", os.path.join(SAGE_TMP, 'test'))
    sage: load(objfile)
    'A python string'
    sage: load(objfile_short)
    'A python string'
    TESTS:
    Check that trac ticket #11577 is fixed:
    sage: filename = os.path.join(SAGE_TMP, "foo.bar") # filename containing a dot
                                              # saves tuple to "foo.bar.sobj"
    sage: save((1,1),filename)
    sage: load(filename)
     (1, 1)
sage.structure.sage object.unpickle all(dir=None, debug=False, run test suite=False)
    Unpickle all sobj's in the given directory, reporting failures as they occur. Also printed the number of successes
    and failure.
    INPUT:
        •dir – a string; the name of a directory (or of a .tar.bz2 file that decompresses to a directory) full of pickles.
         (default: the standard pickle jar)
        •debug – a boolean (default: False) whether to report a stacktrace in case of failure
        •run_test_suite - a boolean (default: False) whether to run TestSuite(x).run() on the un-
         pickled objects
```

EXAMPLES:

```
sage: dir = tmp_dir()
sage: sage.structure.sage_object.picklejar('hello', dir)
sage: sage.structure.sage_object.unpickle_all(dir)
Successfully unpickled 1 objects.
Failed to unpickle 0 objects.
```

When run with no arguments unpickle_all() tests that all of the "standard" pickles stored in the pickle_jar at SAGE_ROOT/local/share/sage/ext/pickle_jar/pickle_jar.tar.bz2 can be unpickled.

```
sage: sage.structure.sage_object.unpickle_all() # (4s on sage.math, 2011)
doctest:... DeprecationWarning: This class is replaced by Matrix_modn_dense_float/Matrix_modn_de
See http://trac.sagemath.org/4260 for details.
Successfully unpickled ... objects.
Failed to unpickle 0 objects.
When it is not possible to unpickle a pickle in the pickle is then uppickle a all () prints the follow.
```

When it is not possible to unpickle a pickle in the pickle_jar then unpickle_all() prints the following error message which warns against removing pickles from the pickle_jar and directs the user towards register_unpickle_override(). The following code intentionally breaks a pickle to illustrate this:

```
sage: from sage.structure.sage_object import register_unpickle_override, unpickle_all, unpickle_
sage: class A(CombinatorialObject, sage.structure.element.Element):
         pass # to break a pickle
sage: tableau_unpickler=unpickle_global('sage.combinat.tableau','Tableau_class')
sage: register_unpickle_override('sage.combinat.tableau','Tableau_class',A) # breaking the pickle
sage: unpickle_all() # todo: not tested
. . .
Failed:
_class__sage_combinat_crystals_affine_AffineCrystalFromClassicalAndPromotion_with_category_eleme
_class__sage_combinat_crystals_tensor_product_CrystalOfTableaux_with_category_element_class__.sc
_class__sage_combinat_crystals_tensor_product_TensorProductOfCrystalsWithGenerators_with_categor
_class__sage_combinat_tableau_Tableau_class__.sobj
\star\star This error is probably due to an old pickle failing to unpickle.
** See sage.structure.sage_object.register_unpickle_override for
** how to override the default unpickling methods for (old) pickles.
** NOTE: pickles should never be removed from the pickle_jar!
Successfully unpickled 583 objects.
Failed to unpickle 4 objects.
sage: register_unpickle_override('sage.combinat.tableau','Tableau_class',tableau_unpickler) # re
```

Todo

Create a custom-made SourPickle for the last example.

If you want to find *lots* of little issues in Sage then try the following:

```
sage: print "x"; sage.structure.sage_object.unpickle_all(run_test_suite = True) # todo: not test
```

This runs TestSuite tests on all objects in the Sage pickle jar. Some of those objects seem to unpickle properly, but do not pass the tests because their internal data structure is messed up. In most cases though it is just that their source file misses a TestSuite call, and therefore some misfeatures went unnoticed (typically Parents not implementing the an_element method).

Note: Every so often the standard pickle jar should be updated by running the doctest suite with the environment variable SAGE_PICKLE_JAR set, then copying the files from SAGE_ROOT/tmp/pickle_jar* into the standard pickle jar.

Warning: Sage's pickle jar helps to ensure backward compatibility in sage. Pickles should **only** be removed from the pickle jar after the corresponding objects have been properly deprecated. Any proposal to remove pickles from the pickle jar should first be discussed on sage-devel.

```
sage.structure.sage_object.unpickle_global(module, name)
```

Given a module name and a name within that module (typically a class name), retrieve the corresponding object.

This normally just looks up the name in the module, but it can be overridden by register_unpickle_override. This is used in the Sage unpickling mechanism, so if the Sage source code organization changes, register_unpickle_override can allow old pickles to continue to work.

EXAMPLES:

```
sage: from sage.structure.sage_object import unpickle_override, register_unpickle_override
sage: unpickle_global('sage.rings.integer', 'Integer')
<type 'sage.rings.integer.Integer'>
```

Now we horribly break the pickling system:

```
sage: register_unpickle_override('sage.rings.integer', 'Integer', Rational, call_name=('sage.rings.integer', 'Integer')
<type 'sage.rings.rational.Rational'>
```

and we reach into the internals and put it back:

```
sage: del unpickle_override[('sage.rings.integer', 'Integer')]
sage: unpickle_global('sage.rings.integer', 'Integer')
<type 'sage.rings.integer.Integer'>
```

BASE CLASS FOR OBJECTS OF A CATEGORY

Base class for objects of a category

CLASS HIERARCHY:

- SageObject
 - CategoryObject
 - * Parent

Many category objects in Sage are equipped with generators, which are usually special elements of the object. For example, the polynomial ring $\mathbf{Z}[x,y,z]$ is generated by x,y, and z. In Sage the i th generator of an object X is obtained using the notation X. gen (i). From the Sage interactive prompt, the shorthand notation X. i is also allowed.

The following examples illustrate these functions in the context of multivariate polynomial rings and free modules.

EXAMPLES:

```
sage: R = PolynomialRing(ZZ, 3, 'x')
sage: R.ngens()
3
sage: R.gen(0)
x0
sage: R.gens()
(x0, x1, x2)
sage: R.variable_names()
('x0', 'x1', 'x2')
```

This example illustrates generators for a free module over Z.

```
sage: M = FreeModule(ZZ, 4)
sage: M
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: M.ngens()
4
sage: M.gen(0)
(1, 0, 0, 0)
sage: M.gens()
((1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1))
```

class sage.structure.category_object.CategoryObject

Bases: sage.structure.sage_object.SageObject

An object in some category.

```
Hom (codomain, cat=None)
```

Return the homspace <code>Hom(self, codomain, cat)</code> of all homomorphisms from self to codomain in the category cat. The default category is determined by <code>self.category()</code> and <code>codomain.category()</code>.

EXAMPLES:

```
sage: R.\langle x,y \rangle = PolynomialRing(QQ, 2)
sage: R.Hom(QQ)
Set of Homomorphisms from Multivariate Polynomial Ring in x, y over Rational Field to Ration
```

Homspaces are defined for very general Sage objects, even elements of familiar rings.

```
sage: n = 5; Hom(n,7)
Set of Morphisms from 5 to 7 in Category of elements of Integer Ring
sage: z=(2/3); Hom(z,8/1)
Set of Morphisms from 2/3 to 8 in Category of elements of Rational Field
```

This example illustrates the optional third argument:

```
sage: QQ.Hom(ZZ, Sets())
Set of Morphisms from Rational Field to Integer Ring in Category of sets
```

base()

base_ring()

Return the base ring of self.

INPUT:

•self – an object over a base ring; typically a module

EXAMPLES:

```
sage: from sage.modules.module import Module
sage: Module(ZZ).base_ring()
Integer Ring
sage: F = FreeModule(ZZ,3)
sage: F.base_ring()
Integer Ring
sage: F.__class__.base_ring
<method 'base_ring' of 'sage.structure.category_object.CategoryObject' objects>
sage: F = FreeAlgebra(QQ, 'x')
sage: F.base_ring()
Rational Field
sage: F.__class__.base_ring
<method 'base_ring' of 'sage.structure.category_object.CategoryObject' objects>
sage: E = CombinatorialFreeModule(ZZ, [1,2,3])
sage: F = CombinatorialFreeModule(ZZ, [2,3,4])
sage: H = Hom(E, F)
sage: H.base_ring()
Integer Ring
sage: H.__class__.base_ring
<method 'base_ring' of 'sage.structure.category_object.CategoryObject' objects>
```

Todo

Move this method elsewhere (typically in the Modules category) so as not to pollute the namespace of all

category objects.

```
categories()
```

Return the categories of self.

EXAMPLES:

```
sage: ZZ.categories()
[Category of euclidean domains,
    Category of principal ideal domains,
    Category of unique factorization domains,
    Category of gcd domains,
    Category of integral domains,
    Category of domains,
    Category of commutative rings, ...
    Category of monoids, ...,
    Category of sets, ...,
    Category of objects]

category()
gens_dict()
    Return a dictionary whose entries are {var_name:variable, ...}.
```

gens_dict_recursive()

Return the dictionary of generators of self and its base rings.

OUTPUT

•a dictionary with string names of generators as keys and generators of self and its base rings as values.

EXAMPLES:

```
sage: R = QQ['x,y']['z,w']
sage: sorted(R.gens_dict_recursive().items())
[('w', w), ('x', x), ('y', y), ('z', z)]
```

has base(category=None)

```
inject_variables (scope=None, verbose=True)
```

Inject the generators of self with their names into the namespace of the Python code from which this function is called. Thus, e.g., if the generators of self are labeled 'a', 'b', and 'c', then after calling this method the variables a, b, and c in the current scope will be set equal to the generators of self.

NOTE: If Foo is a constructor for a Sage object with generators, and Foo is defined in Cython, then it would typically call $inject_variables()$ on the object it creates. E.g., PolynomialRing(QQ, 'y') does this so that the variable y is the generator of the polynomial ring.

```
injvar (scope=None, verbose=True)
```

This is a deprecated synonym for inject_variables().

```
latex_name()
```

latex_variable_names()

Returns the list of variable names suitable for latex output.

All _SOMETHING substrings are replaced by _{SOMETHING} recursively so that subscripts of subscripts work.

EXAMPLES:

```
sage: R, x = PolynomialRing(QQ, 'x', 12).objgens()
                       sage: x
                       (x0, x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11)
                       sage: print R.latex_variable_names ()
                        ['x_{0}', 'x_{1}', 'x_{2}', 'x_{3}', 'x_{4}', 'x_{5}', 'x_{6}', 'x_{7}', 'x_{8}', 'x_{9}', 'x_{9}', 'x_{1}', 
                       sage: f = x[0]^3 + 15/3 * x[1]^10
                       sage: print latex(f)
                       5 x_{1}^{1} + x_{0}^{3}
            normalize_names (ngens, names=None)
            objgen()
                       Return the tuple (self, self.gen()).
                       EXAMPLES:
                       sage: R, x = PolynomialRing(QQ,'x').objgen()
                       Univariate Polynomial Ring in x over Rational Field
                       sage: x
                       Х
            objgens()
                       Return the tuple (self, self.gens()).
                       EXAMPLES:
                       sage: R = PolynomialRing(QQ, 3, 'x'); R
                       Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
                       sage: R.objgens()
                        (Multivariate Polynomial Ring in x0, x1, x2 over Rational Field, (x0, x1, x2))
            variable_name()
            variable_names()
sage.structure.category_object.check_default_category (default_category, category)
sage.structure.category_object.guess_category(obj)
class sage.structure.category_object.localvars(obj, names, latex_names=None, normal-
                                                                                                                                       ize=True)
            Context manager for safely temporarily changing the variables names of an object with generators.
            Objects with named generators are globally unique in Sage. Sometimes, though, it is very useful to be able
```

Objects with named generators are globally unique in Sage. Sometimes, though, it is very useful to be able to temporarily display the generators differently. The new Python with statement and the localvars context manager make this easy and safe (and fun!)

```
Suppose X is any object with generators. Write
```

```
with localvars(X, names[, latex_names] [,normalize=False]):
    some code
...
```

and the indented code will be run as if the names in X are changed to the new names. If you give normalize=True, then the names are assumed to be a tuple of the correct number of strings.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: with localvars(R, 'z,w'):
... print x^3 + y^3 - x*y
```

```
z^3 + w^3 - z*w
```

NOTES: I wrote this because it was needed to print elements of the quotient of a ring R by an ideal I using the print function for elements of R. See the code in sage.rings.quotient_ring_element.

AUTHOR: William Stein (2006-10-31)

Sage Reference Manual: Basic Structures, Release 6.3					

BASE CLASS FOR OLD-STYLE PARENT OBJECTS

Base class for old-style parent objects

CLASS HIERARCHY:

SageObject

Parent

ParentWithBase ParentWithGens

TESTS:

This came up in some subtle bug once.

```
sage: gp(2) + gap(3)
5

class sage.structure.parent_old.Parent
    Bases: sage.structure.parent.Parent
```

Parents are the SAGE/mathematical analogues of container objects in computer science.

TESTS:

```
sage: V = VectorSpace(GF(2,'a'),2)
sage: V.list()
[(0, 0), (1, 0), (0, 1), (1, 1)]
sage: MatrixSpace(GF(3), 1, 1).list()
[[0], [1], [2]]
sage: DirichletGroup(3).list()
[Dirichlet character modulo 3 of conductor 1 mapping 2 |--> 1,
Dirichlet character modulo 3 of conductor 3 mapping 2 |--> -1]
sage: K = GF(7^6,'a')
sage: K.list()[:10] # long time
[0, 1, 2, 3, 4, 5, 6, a, a + 1, a + 2]
sage: K.<a> = GF(4)
sage: K.list()
[0, a, a + 1, 1]
```

 $\verb"coerce_map_from_c"\,(S)$

EXAMPLES:

Check to make sure that we handle coerce maps from Python native types correctly:

sage: QQ['q,t'].coerce_map_from(int)

```
Composite map:
      From: Set of Python objects of type 'int'
             Multivariate Polynomial Ring in q, t over Rational Field
      Defn: Native morphism:
                From: Set of Python objects of type 'int'
                     Rational Field
              then
                Polynomial base injection morphism:
                From: Rational Field
                     Multivariate Polynomial Ring in q, t over Rational Field
coerce_map_from_impl(S)
get_action_c (S, op, self_on_left)
get_action_impl(S, op, self_on_left)
has\_coerce\_map\_from\_c(S)
    Return True if there is a natural map from S to self. Otherwise, return False.
has_coerce_map_from_impl(S)
list()
    Return a list of the elements of self.
    A list of all the elements produced by the iterator defined for the object. The result is cached. An infinite
    set may define an iterator, allowing one to search through the elements, but a request by this method for
    the entire list should fail.
    NOTE:
    Some objects X do not know if they are finite or not.
                                                               If X.is_finite() fails with a
    NotImplementedError, then X.list() will simply try. In that case, it may run without stopping.
    However, if X knows that it is infinite, then running X.list() will raise an appropriate error, while
```

Nevertheless, since the whole list of elements is created and cached by X.list(), it may be better to do for x in X:, not for x in X.list():.

running list (X) will run indefinitely. For many Sage objects X, using X.list () is preferable to using

EXAMPLES:

list(X).

```
sage: R = Integers(11)
sage: R.list()  # indirect doctest
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: ZZ.list()
Traceback (most recent call last):
...
ValueError: since it is infinite, cannot list Integer Ring

This is the motivation for trac ticket #10470
sage: (QQ^2).list()
Traceback (most recent call last):
...
ValueError: since it is infinite, cannot list Vector space of dimension 2 over Rational Field
```

TESTS:

The following tests the caching by adjusting the cached version:

```
sage: R = Integers(3)
sage: R.list()
[0, 1, 2]
sage: R._list[0] = 'junk'
sage: R.list()
['junk', 1, 2]
```

Here we test that for an object that does not know whether it is finite or not. Calling X.list() simply tries to create the list (but here it fails, since the object is not iterable). This was fixed trac ticket #11350

```
sage: R.<t,p> = QQ[]
sage: Q = R.quotient(t^2-t+1)
sage: Q.is_finite()
Traceback (most recent call last):
...
NotImplementedError
sage: Q.list()
Traceback (most recent call last):
...
NotImplementedError: object does not support iteration
```

Here is another example. We artificially create a version of the ring of integers that does not know whether it is finite or not:

Asking for list (MyIntegers) below will never finish without pressing Ctrl-C. We let it run for 1 second and then interrupt:

```
sage: alarm(1.0); list(MyIntegers)
Traceback (most recent call last):
...
AlarmInterrupt
```

CHAPTER

FOUR

BASE CLASS FOR OLD-STYLE PARENT OBJECTS WITH A BASE RING

Base class for old-style parent objects with a base ring

 ${\bf class} \; {\tt sage.structure.parent_base.ParentWithBase}$

Bases: sage.structure.parent_old.Parent

This class is being deprecated, see parent.Parent for the new model.

 $base_extend(X)$

 $\verb|sage.structure.parent_base.is_ParentWithBase| (x)$

Return True if x is a parent object with base.

BASE CLASS FOR OLD-STYLE PARENT OBJECTS WITH GENERATORS

Base class for old-style parent objects with generators

Note: This class is being deprecated, see sage.structure.parent.Parent and sage.structure.category_object.CategoryObject for the new model.

Many parent objects in Sage are equipped with generators, which are special elements of the object. For example, the polynomial ring $\mathbf{Z}[x,y,z]$ is generated by x, y, and z. In Sage the i^{th} generator of an object X is obtained using the notation X. gen(i). From the Sage interactive prompt, the shorthand notation X. i is also allowed.

REQUIRED: A class that derives from ParentWithGens *must* define the ngens() and gen(i) methods.

OPTIONAL: It is also good if they define gens() to return all gens, but this is not necessary.

The gens function returns a tuple of all generators, the ngens function returns the number of generators.

The _assign_names functions is for internal use only, and is called when objects are created to set the generator names. It can only be called once.

The following examples illustrate these functions in the context of multivariate polynomial rings and free modules.

EXAMPLES:

```
sage: R = PolynomialRing(ZZ, 3, 'x')
sage: R.ngens()
3
sage: R.gen(0)
x0
sage: R.gens()
(x0, x1, x2)
sage: R.variable_names()
('x0', 'x1', 'x2')
```

This example illustrates generators for a free module over **Z**.

```
sage: M = FreeModule(ZZ, 4)
sage: M
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: M.ngens()
4
```

```
sage: M.gen(0)
(1, 0, 0, 0)
sage: M.gens()
((1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1))
class sage.structure.parent_gens.ParentWithAdditiveAbelianGens
    Bases: sage.structure.parent_gens.ParentWithGens
    EXAMPLES:
    sage: class MyParent (ParentWithGens):
              def ngens(self): return 3
    sage: P = MyParent(base = QQ, names = 'a,b,c', normalize = True, category = Groups())
    sage: P.category()
    Category of groups
    sage: P._names
     ('a', 'b', 'c')
    generator_orders()
class sage.structure.parent_gens.ParentWithGens
    Bases: sage.structure.parent_base.ParentWithBase
    EXAMPLES:
    sage: class MyParent (ParentWithGens):
              def ngens(self): return 3
    sage: P = MyParent(base = QQ, names = 'a,b,c', normalize = True, category = Groups())
    sage: P.category()
    Category of groups
    sage: P._names
     ('a', 'b', 'c')
    gen(i=0)
    gens()
         Return a tuple whose entries are the generators for this object, in order.
```

hom (im_gens, codomain=None, check=True)

Return the unique homomorphism from self to codomain that sends self.gens() to the entries of im_gens. Raises a TypeError if there is no such homomorphism.

INPUT:

- $\verb| •im_gens| the images in the codomain of the generators of this object under the homomorphism$
- •codomain the codomain of the homomorphism
- •check whether to verify that the images of generators extend to define a map (using only canonical coercions).

OUTPUT:

•a homomorphism self -> codomain

Note: As a shortcut, one can also give an object X instead of im_gens, in which case return the (if it exists) natural map to X.

EXAMPLE: Polynomial Ring We first illustrate construction of a few homomorphisms involving a polynomial ring.

```
sage: R.<x> = PolynomialRing(ZZ)
         sage: f = R.hom([5], QQ)
         sage: f(x^2 - 19)
         sage: R.<x> = PolynomialRing(QQ)
         sage: f = R.hom([5], GF(7))
         Traceback (most recent call last):
         TypeError: images do not define a valid homomorphism
         sage: R. < x > = PolynomialRing(GF(7))
         sage: f = R.hom([3], GF(49,'a'))
         sage: f
         Ring morphism:
          From: Univariate Polynomial Ring in x over Finite Field of size 7
          To: Finite Field in a of size 7^2
          Defn: x \mid --> 3
         sage: f(x+6)
         sage: f(x^2+1)
         EXAMPLE: Natural morphism
         sage: f = ZZ.hom(GF(5))
         sage: f(7)
         sage: f
         Ring Coercion morphism:
          From: Integer Ring
          To: Finite Field of size 5
         There might not be a natural morphism, in which case a TypeError exception is raised.
         sage: 00.hom(ZZ)
         Traceback (most recent call last):
         TypeError: Natural coercion morphism from Rational Field to Integer Ring not defined.
    ngens()
class sage.structure.parent_gens.ParentWithMultiplicativeAbelianGens
    Bases: sage.structure.parent_gens.ParentWithGens
    EXAMPLES:
    sage: class MyParent (ParentWithGens):
             def ngens(self): return 3
    sage: P = MyParent(base = QQ, names = 'a,b,c', normalize = True, category = Groups())
    sage: P.category()
    Category of groups
    sage: P._names
     ('a', 'b', 'c')
    generator orders()
sage.structure.parent_gens.is_ParentWithAdditiveAbelianGens(x)
    Return True if x is a parent object with additive abelian generators, i.e., derives from
    sage.structure.parent_gens.ParentWithAdditiveAbelianGens and False otherwise.
```

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithAdditiveAbelianGens
sage: is_ParentWithAdditiveAbelianGens(QQ)
False
sage: is_ParentWithAdditiveAbelianGens(QQ^3)
True
```

sage.structure.parent_gens.is_ParentWithGens(x)

Return True if x is a parent object with generators, i.e., derives from sage.structure.parent_gens.ParentWithGens and False otherwise.

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithGens
sage: is_ParentWithGens(QQ['x'])
True
sage: is_ParentWithGens(CC)
True
sage: is_ParentWithGens(Primes())
False
```

sage.structure.parent_gens.is_ParentWithMultiplicativeAbelianGens(x)

Return True if x is a parent object with additive abelian generators, i.e., derives from sage.structure.parent_gens.ParentWithMultiplicativeAbelianGens and False otherwise.

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithMultiplicativeAbelianGens
sage: is_ParentWithMultiplicativeAbelianGens(QQ)
False
sage: is_ParentWithMultiplicativeAbelianGens(DirichletGroup(11))
True
```

class sage.structure.parent_gens.localvars

Bases: object

Context manager for safely temporarily changing the variables names of an object with generators.

Objects with named generators are globally unique in Sage. Sometimes, though, it is very useful to be able to temporarily display the generators differently. The new Python with statement and the localvars context manager make this easy and safe (and fun!)

Suppose X is any object with generators. Write

```
with localvars(X, names[, latex_names] [,normalize=False]):
    some code
    ...
```

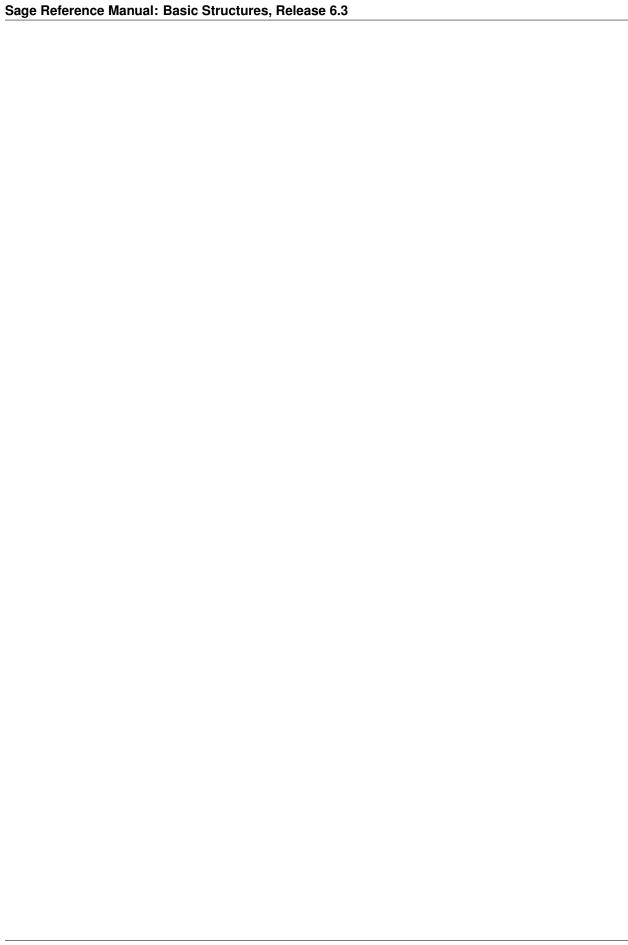

and the indented code will be run as if the names in X are changed to the new names. If you give normalize=True, then the names are assumed to be a tuple of the correct number of strings.

EXAMPLES:

Note: I wrote this because it was needed to print elements of the quotient of a ring R by an ideal I using the print function for elements of R. See the code in quotient_ring_element.pyx.

```
AUTHOR:
         •William Stein (2006-10-31)
sage.structure.parent_gens.normalize_names (ngens, names=None)
     Return a tuple of strings of variable names of length ngens given the input names.
     INPUT:
         •ngens - integer
         •names
            -tuple or list of strings, such as ('x', 'y')
            -a string prefix, such as 'alpha'
            -string of single character names, such as 'xyz'
     EXAMPLES:
     sage: from sage.structure.parent_gens import normalize_names as nn
     sage: nn(1, 'a')
     ('a',)
     sage: nn(2, 'zzz')
     ('zzz0', 'zzz1')
     sage: nn(2, 'ab')
     ('a', 'b')
     sage: nn(3, ('a', 'bb', 'ccc'))
     ('a', 'bb', 'ccc')
     sage: nn(4, ['al', 'a2', 'b1', 'b11'])
     ('a1', 'a2', 'b1', 'b11')
     TESTS:
     sage: nn(2, 'z1')
     ('z10', 'z11')
     sage: PolynomialRing(QQ, 2, 'alpha0')
```

Multivariate Polynomial Ring in alpha00, alpha01 over Rational Field

CONTAINERS FOR STORING COERCION DATA

Containers for storing coercion data

This module provides TripleDict and MonoDict. These are structures similar to WeakKeyDictionary in Python's weakref module, and are optimized for lookup speed. The keys for TripleDict consist of triples (k1,k2,k3) and are looked up by identity rather than equality. The keys are stored by weakrefs if possible. If any one of the components k1, k2, k3 gets garbage collected, then the entry is removed from the TripleDict.

Key components that do not allow for weakrefs are stored via a normal refcounted reference. That means that any entry stored using a triple (k1,k2,k3) so that none of the k1,k2,k3 allows a weak reference behaves as an entry in a normal dictionary: Its existence in TripleDict prevents it from being garbage collected.

That container currently is used to store coercion and conversion maps between two parents (trac ticket #715) and to store homsets of pairs of objects of a category (trac ticket #11521). In both cases, it is essential that the parent structures remain garbage collectable, it is essential that the data access is faster than with a usual WeakKeyDictionary, and we enforce the "unique parent condition" in Sage (parent structures should be identical if they are equal).

MonoDict behaves similarly, but it takes a single item as a key. It is used for caching the parents which allow a coercion map into a fixed other parent (trac ticket #12313).

By trac ticket #14159, MonoDict and TripleDict can be optionally used with weak references on the values.

```
class sage.structure.coerce_dict.MonoDict
    Bases: object
```

This is a hashtable specifically designed for (read) speed in the coercion model.

It differs from a python WeakKeyDictionary in the following important ways:

- •Comparison is done using the 'is' rather than '==' operator.
- •Only weak references to the keys are stored if at all possible. Keys that do not allow for weak references are stored with a normal refcounted reference.
- •The callback of the weak references is safe against recursion, see below.

There are special cdef set/get methods for faster access. It is bare-bones in the sense that not all dictionary methods are implemented.

IMPLEMENTATION:

It is implemented as a hash table with open addressing, similar to python's dict.

If ki supports weak references then ri is a weak reference to ki with a callback to remove the entry from the dictionary if ki gets garbage collected. If ki is does not support weak references then ri

is identical to ki. In the latter case the presence of the key in the dictionary prevents it from being garbage collected.

INPUT:

- •size unused parameter, present for backward compatibility.
- •data optional iterable defining initial data.
- •threshold unused parameter, present for backward compatibility.
- •weak_values optional bool (default False). If it is true, weak references to the values in this dictionary will be used, when possible.

EXAMPLES:

```
sage: from sage.structure.coerce_dict import MonoDict
sage: L = MonoDict()
sage: a = 'a'; b = 'ab'; c = -15
sage: L[a] = 1
sage: L[b] = 2
sage: L[c] = 3
```

The key is expected to be a unique object. Hence, the item stored for c can not be obtained by providing another equal number:

```
sage: L[a]
1
sage: L[b]
2
sage: L[c]
3
sage: L[-15]
Traceback (most recent call last):
...
KeyError: -15
```

Not all features of Python dictionaries are available, but iteration over the dictionary items is possible:

```
sage: # for some reason the following failed in "make ptest"
sage: # on some installations, see #12313 for details
sage: sorted(L.iteritems()) # random layout
[(-15, 3), ('a', 1), ('ab', 2)]
sage: # the following seems to be more consistent
sage: set(L.iteritems())
set([('a', 1), ('ab', 2), (-15, 3)])
sage: del L[c]
sage: sorted(L.iteritems())
[('a', 1), ('ab', 2)]
sage: len(L)
sage: for i in range(1000):
         L[i] = i
. . .
sage: len(L)
1002
sage: L['a']
```

```
sage: L['c']
Traceback (most recent call last):
...
KeyError: 'c'
```

Note that this kind of dictionary is also used for caching actions and coerce maps. In previous versions of Sage, the cache was by strong references and resulted in a memory leak in the following example. However, this leak was fixed by trac ticket #715, using weak references:

```
sage: K = GF(1<<55,'t')
sage: for i in range(50):
...     a = K.random_element()
...     E = EllipticCurve(j=a)
...     P = E.random_point()
...     Q = 2*P
sage: import gc
sage: n = gc.collect()
sage: from sage.schemes.elliptic_curves.ell_finite_field import EllipticCurve_finite_field
sage: LE = [x for x in gc.get_objects() if isinstance(x, EllipticCurve_finite_field)]
sage: len(LE)  # indirect doctest
</pre>
```

TESTS:

Here, we demonstrate the use of weak values.

```
sage: M = MonoDict(13)
sage: MW = MonoDict(13, weak_values=True)
sage: class Foo: pass
sage: a = Foo()
sage: b = Foo()
sage: k = 1
sage: M[k] = a
sage: MW[k] = b
sage: M[k] is a
True
sage: MW[k] is b
True
sage: k in M
True
sage: k in MW
True
```

While M uses a strong reference to a, MW uses a *weak* reference to b, and after deleting b, the corresponding item of MW will be removed during the next garbage collection:

```
sage: import gc
sage: del a,b
sage: _ = gc.collect()
sage: k in M
True
sage: k in MW
False
sage: len(MW)
```

```
sage: len(M)
Note that MW also accepts values that do not allow for weak references:
    sage: MW[k] = int(5)
    sage: MW[k]
    5
The following demonstrates that :class: 'MonoDict' is safer than
:class:'~weakref.WeakKeyDictionary' against recursions created by nested
callbacks; compare :trac: '15069' (the mechanism used now is different, though)::
    sage: M = MonoDict(11)
    sage: class A: pass
    sage: a = A()
    sage: prev = a
    sage: for i in range(1000):
             newA = A()
            M[prev] = newA
    . . . . :
             prev = newA
    . . . . :
    sage: len(M)
    1000
    sage: del a
    sage: len(M)
The corresponding example with a Python :class: 'weakref.WeakKeyDictionary'
would result in a too deep recursion during deletion of the dictionary
items::
    sage: import weakref
    sage: M = weakref.WeakKeyDictionary()
    sage: a = A()
    sage: prev = a
    sage: for i in range(1000):
            newA = A()
             M[prev] = newA
             prev = newA
    . . . . :
    sage: len(M)
    1000
    sage: del a
    Exception RuntimeError: 'maximum recursion depth exceeded while calling a Python object' in
    sage: len(M) > 0
    True
Check that also in the presence of circular references, :class:'MonoDict'
gets properly collected::
    sage: import gc
    sage: def count_type(T):
              return len([c for c in gc.get_objects() if isinstance(c,T)])
    sage: _=gc.collect()
    sage: N=count_type(MonoDict)
    sage: for i in range(100):
    ....: V = [MonoDict(11, {"id": j+100*i}) for j in range(100)]
              n=len(V)
    . . . . :
```

```
for i in range(n): V[i][V[(i+1)%n]]=(i+1)%n
         . . . . :
         . . . . :
                  del V
                   _=gc.collect()
         . . . . :
                   assert count_type(MonoDict) == N
         sage: count_type(MonoDict) == N

    - Simon King (2013-02)
    - Nils Bruin (2013-11)
    iteritems()
         EXAMPLES:
         sage: from sage.structure.coerce_dict import MonoDict
         sage: L = MonoDict(31)
         sage: L[1] = None
         sage: L[2] = True
         sage: list(sorted(L.iteritems()))
         [(1, None), (2, True)]
class sage.structure.coerce_dict.MonoDictEraser
    Bases: object
```

Erase items from a MonoDict when a weak reference becomes invalid.

This is of internal use only. Instances of this class will be passed as a callback function when creating a weak reference.

EXAMPLES:

Bases: object

```
sage: from sage.structure.coerce_dict import MonoDict
    sage: class A: pass
    sage: a = A()
    sage: M = MonoDict()
    sage: M[a] = 1
    sage: len(M)
    1
    sage: del a
    sage: import qc
    sage: n = gc.collect()
    sage: len(M)
                  # indirect doctest
    AUTHOR:
        •Simon King (2012-01)
        •Nils Bruin (2013-11)
class sage.structure.coerce_dict.TripleDict
```

This is a hashtable specifically designed for (read) speed in the coercion model.

It differs from a python dict in the following important ways:

•All keys must be sequence of exactly three elements. All sequence types (tuple, list, etc.) map to the same item.

•Comparison is done using the 'is' rather than '==' operator.

There are special cdef set/get methods for faster access. It is bare-bones in the sense that not all dictionary methods are implemented.

It is implemented as a list of lists (hereafter called buckets). The bucket is chosen according to a very simple hash based on the object pointer, and each bucket is of the form [id(k1), id(k2), id(k3), r1, r2, r3, value, id(k1), id(k2), id(k3), r1, r2, r3, value, ...], on which a linear search is performed. If a key component ki supports weak references then ri is a weak reference to ki; otherwise ri is identical to ki.

INPUT:

- •size an integer, the initial number of buckets. To spread objects evenly, the size should ideally be a prime, and certainly not divisible by 2.
- •data optional iterable defining initial data.
- •threshold optional number, default 0.7. It determines how frequently the dictionary will be resized (large threshold implies rare resizing).
- •weak_values optional bool (default False). If it is true, weak references to the values in this dictionary will be used, when possible.

If any of the key components k1,k2,k3 (this can happen for a key component that supports weak references) gets garbage collected then the entire entry disappears. In that sense this structure behaves like a nested WeakKeyDictionary.

```
sage: from sage.structure.coerce_dict import TripleDict
sage: L = TripleDict()
sage: a = 'a'; b = 'b'; c = 'c'
sage: L[a,b,c] = 1
sage: L[a,b,c]
sage: L[c,b,a] = -1
sage: list(L.iteritems())
                            # random order of output.
[(('c', 'b', 'a'), -1), (('a', 'b', 'c'), 1)]
sage: del L[a,b,c]
sage: list(L.iteritems())
[(('c', 'b', 'a'), -1)]
sage: len(L)
1
sage: for i in range(1000):
      L[i,i,i] = i
. . .
sage: len(L)
sage: L = TripleDict(L)
sage: L[c,b,a]
sage: L[a,b,c]
Traceback (most recent call last):
KeyError: ('a', 'b', 'c')
sage: L[a]
Traceback (most recent call last):
KeyError: 'a'
sage: L[a] = 1
Traceback (most recent call last):
. . .
KeyError: 'a'
```

Note that this kind of dictionary is also used for caching actions and coerce maps. In previous versions of Sage, the cache was by strong references and resulted in a memory leak in the following example. However, this leak was fixed by trac ticket #715, using weak references:

```
sage: K = GF(1<<55,'t')
sage: for i in range(50):
...     a = K.random_element()
...     E = EllipticCurve(j=a)
...     P = E.random_point()
...     Q = 2*P
sage: import gc
sage: n = gc.collect()
sage: from sage.schemes.elliptic_curves.ell_finite_field import EllipticCurve_finite_field
sage: LE = [x for x in gc.get_objects() if isinstance(x, EllipticCurve_finite_field)]
sage: len(LE)  # indirect doctest</pre>
```

TESTS:

Here, we demonstrate the use of weak values.

```
sage: class Foo: pass
sage: T = TripleDict(13)
sage: TW = TripleDict(13, weak_values=True)
sage: a = Foo()
sage: b = Foo()
sage: k = 1
sage: T[a,k,k]=1
sage: T[k,a,k]=2
sage: T[k,k,a]=3
sage: T[k,k,k]=a
sage: TW[b,k,k]=1
sage: TW[k,b,k]=2
sage: TW[k,k,b]=3
sage: TW[k,k,k]=b
sage: len(T)
4
sage: len(TW)
sage: (k,k,k) in T
True
sage: (k,k,k) in TW
True
sage: T[k,k,k] is a
True
sage: TW[k,k,k] is b
True
```

Now, T holds a strong reference to a, namely in T[k,k,k]. Hence, when we delete a, all items of T survive:

```
sage: del a
sage: _ = gc.collect()
sage: len(T)
4
```

Only when we remove the strong reference, the items become collectable:

```
sage: del T[k,k,k]
sage: _ = gc.collect()
sage: len(T)
0
```

The situation is different for TW, since it only holds *weak* references to a. Therefore, all items become collectable after deleting a:

```
sage: del b
sage: _ = gc.collect()
sage: len(TW)
0
```

Note: The index h corresponding to the key [k1, k2, k3] is computed as a value of unsigned type size_t as follows:

```
h = id(k1) + 13 * id(k2)xor503id(k3)
```

The natural type for this quantity is Py_ssize_t, which is a signed quantity with the same length as size_t. Storing it in a signed way gives the most efficient storage into PyInt, while preserving sign information.

In previous situations there were some problems with ending up with negative indices, which required casting to an unsigned type, i.e., (<size_t> h)% N since C has a sign-preserving % operation This caused problems on 32 bits systems, see trac ticket #715 for details. This is irrelevant for the current implementation.

iteritems()

EXAMPLES:

```
sage: from sage.structure.coerce_dict import TripleDict
sage: L = TripleDict(31)
sage: L[1,2,3] = None
sage: list(L.iteritems())
[((1, 2, 3), None)]
```

class sage.structure.coerce_dict.TripleDictEraser

Bases: object

Erases items from a TripleDict when a weak reference becomes invalid.

This is of internal use only. Instances of this class will be passed as a callback function when creating a weak reference.

```
sage: from sage.structure.coerce_dict import TripleDict
sage: class A: pass
sage: a = A()
sage: T = TripleDict()
sage: T[a, ZZ, None] = 1
sage: T[ZZ,a,1] = 2
sage: T[a,a,ZZ] = 3
sage: len(T)
3
sage: del a
sage: import gc
```

sage.structure.coerce_dict.signed_id(x)
A function like Python's id() returning *signed* integers, which are guaranteed to fit in a Py_ssize_t.

Theoretically, there is no guarantee that two different Python objects have different signed_id() values.

Theoretically, there is no guarantee that two different Python objects have different signed_id() values. However, under the mild assumption that a C pointer fits in a Py_ssize_t, this is guaranteed.

TESTS:

```
sage: a = 1.23e45  # some object
sage: from sage.structure.coerce_dict import signed_id
sage: s = signed_id(a)
sage: id(a) == s or id(a) == s + 2**32 or id(a) == s + 2**64
True
sage: signed_id(a) <= sys.maxsize
True</pre>
```

Sage Reference Manual: Basic Structures, Release 6.3	

FORMAL SUMS

AUTHORS:

- David Harvey (2006-09-20): changed FormalSum not to derive from "list" anymore, because that breaks new Element interface
- Nick Alexander (2006-12-06): added test cases.
- William Stein (2006, 2009): wrote the first version in 2006, documented it in 2009.
- Volker Braun (2010-07-19): new-style coercions, documentation added. FormalSums now derives from UniqueRepresentation.

FUNCTIONS:

- FormalSums (ring) create the module of formal finite sums with coefficients in the given ring.
- FormalSum(list of pairs (coeff, number)) create a formal sum

EXAMPLES:

True

```
sage: A = FormalSum([(1, 2/3)]); A
sage: B = FormalSum([(3, 1/5)]); B
3 * 1 / 5
sage: -B
-3*1/5
sage: A + B
3*1/5 + 2/3
sage: A - B
-3*1/5 + 2/3
sage: B*3
9 * 1 / 5
sage: 2*A
2*2/3
sage: list(2*A + A)
[(3, 2/3)]
TESTS:
sage: R = FormalSums(QQ)
sage: loads(dumps(R)) == R
sage: a = R(2/3) + R(-5/7); a
-5/7 + 2/3
sage: loads(dumps(a)) == a
```

```
class sage.structure.formal_sum.FormalSum(x, parent=Abelian Group of all Formal Finite Sums
                                                                                                                                        over Integer Ring, check=True, reduce=True)
              Bases: sage.structure.element.ModuleElement
              A formal sum over a ring.
              reduce()
                          EXAMPLES:
                          sage: a = FormalSum([(-2,3), (2,3)], reduce=False); a
                          -2*3 + 2*3
                          sage: a.reduce()
                          sage: a
class sage.structure.formal_sum.FormalSums(base_ring)
                                                                       sage.structure.unique_representation.UniqueRepresentation,
              sage.modules.module_old
              The R-module of finite formal sums with coefficients in some ring R.
              EXAMPLES:
              sage: FormalSums()
              Abelian Group of all Formal Finite Sums over Integer Ring
              sage: FormalSums(ZZ[sqrt(2)])
              Abelian Group of all Formal Finite Sums over Order in Number Field in sqrt2 with defining polynometric polyno
              sage: FormalSums(GF(9,'a'))
              Abelian Group of all Formal Finite Sums over Finite Field in a of size 3^2
             base\_extend(R)
                          EXAMPLES:
                           sage: FormalSums(ZZ).base_extend(GF(7))
                          Abelian Group of all Formal Finite Sums over Finite Field of size 7
```

FACTORIZATIONS

The Factorization class provides a structure for holding quite general lists of objects with integer multiplicities. These may hold the results of an arithmetic or algebraic factorization, where the objects may be primes or irreducible polynomials and the multiplicities are the (non-zero) exponents in the factorization. For other types of examples, see below.

Factorization class objects contain a list, so can be printed nicely and be manipulated like a list of prime-exponent pairs, or easily turned into a plain list. For example, we factor the integer -45:

```
sage: F = factor(-45)
```

This returns an object of type Factorization:

```
sage: type(F)
<class 'sage.structure.factorization_integer.IntegerFactorization'>
```

It prints in a nice factored form:

```
sage: F -1 * 3^2 * 5
```

There is an underlying list representation, emph{which ignores the unit part}:

```
sage: list(F)
[(3, 2), (5, 1)]
```

A Factorization is not actually a list:

```
sage: isinstance(F, list)
False
```

However, we can access the Factorization Fitself as if it were a list:

```
sage: F[0]
(3, 2)
sage: F[1]
(5, 1)
```

To get at the unit part, use the Factorization.unit () function:

```
sage: F.unit()
-1
```

All factorizations are immutable, up to ordering with sort () and simplifying with simplify(). Thus if you write a function that returns a cached version of a factorization, you do not have to return a copy.

```
sage: F = factor(-12); F
-1 * 2^2 * 3
sage: F[0] = (5,4)
Traceback (most recent call last):
...
TypeError: 'Factorization' object does not support item assignment
```

EXAMPLES:

This more complicated example involving polynomials also illustrates that the unit part is not discarded from factorizations:

```
sage: x = QQ['x'].0
sage: f = -5*(x-2)*(x-3)
sage: f
-5*x^2 + 25*x - 30
sage: F = f.factor(); F
(-5) * (x - 3) * (x - 2)
sage: F.unit()
-5
sage: F.value()
-5*x^2 + 25*x - 30
```

The underlying list is the list of pairs (p_i, e_i) , where each p_i is a 'prime' and each e_i is an integer. The unit part is discarded by the list:

```
sage: list(F)
[(x - 3, 1), (x - 2, 1)]
sage: len(F)
2
sage: F[1]
(x - 2, 1)
```

In the ring $\mathbf{Z}[x]$, the integer -5 is not a unit, so the factorization has three factors:

```
sage: x = ZZ['x'].0
sage: f = -5*(x-2)*(x-3)
sage: f
-5*x^2 + 25*x - 30
sage: F = f.factor(); F
(-1) * 5 * (x - 3) * (x - 2)
sage: F.universe()
Univariate Polynomial Ring in x over Integer Ring
sage: F.unit()
-1
sage: list(F)
[(5, 1), (x - 3, 1), (x - 2, 1)]
sage: F.value()
-5*x^2 + 25*x - 30
sage: len(F)
3
```

On the other hand, -1 is a unit in **Z**, so it is included in the unit:

```
sage: x = ZZ['x'].0

sage: f = -1*(x-2)*(x-3)

sage: F = f.factor(); F

(-1)*(x-3)*(x-2)
```

```
sage: F.unit()
-1
sage: list(F)
[(x - 3, 1), (x - 2, 1)]
```

Factorizations can involve fairly abstract mathematical objects:

```
sage: F = ModularSymbols(11,4).factorization()
sage: F
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of
sage: type(F)
<class 'sage.structure.factorization.Factorization'>
sage: K. < a > = NumberField(x^2 + 3); K
Number Field in a with defining polynomial x^2 + 3
sage: f = K.factor(15); f
(Fractional ideal (-a))^2 * (Fractional ideal (5))
sage: f.universe()
Monoid of ideals of Number Field in a with defining polynomial x^2 + 3
sage: f.unit()
Fractional ideal (1)
sage: g=K.factor(9); g
(Fractional ideal (-a))^4
sage: f.lcm(g)
(Fractional ideal (-a)) ^4 * (Fractional ideal (5))
sage: f.gcd(g)
(Fractional ideal (-a))^2
sage: f.is_integral()
True
TESTS:
sage: F = factor(-20); F
-1 * 2^2 * 5
sage: G = loads(dumps(F)); G
-1 * 2^2 * 5
sage: G == F
sage: G is F
False
```

AUTHORS:

- William Stein (2006-01-22): added unit part as suggested by David Kohel.
- William Stein (2008-01-17): wrote much of the documentation and fixed a couple of bugs.
- Nick Alexander (2008-01-19): added support for non-commuting factors.
- John Cremona (2008-08-22): added division, lcm, gcd, is_integral and universe functions

```
class sage.structure.factorization.Factorization(x, unit=None, cr=False, sort=True, simplify=True)
```

```
Bases: \verb|sage.structure.sage_object.SageObject| \\
```

A formal factorization of an object.

```
sage: N = 2006
sage: F = N.factor(); F
2 * 17 * 59
sage: F.unit()
1
sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.unit()
-1
sage: loads(F.dumps()) == F
True
sage: F = Factorization([(x,1/3)])
Traceback (most recent call last):
...
TypeError: exponents of factors must be integers
```

${\tt base_change}\,(U)$

Return the factorization self, with its factors (including the unit part) coerced into the universe U.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.universe()
Integer Ring
sage: P.<x> = ZZ[]
sage: F.base_change(P).universe()
Univariate Polynomial Ring in x over Integer Ring
```

This method will return a TypeError if the coercion is not possible:

```
sage: g = x^2 - 1
sage: F = factor(g); F
(x - 1) * (x + 1)
sage: F.universe()
Univariate Polynomial Ring in x over Integer Ring
sage: F.base_change(ZZ)
Traceback (most recent call last):
...
TypeError: Impossible to coerce the factors of (x - 1) * (x + 1) into Integer Ring
```

${\tt expand}\,(\,)$

Return the product of the factors in the factorization, multiplied out.

EXAMPLES:

```
sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.value()
-2006

sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (x,1)]); F
x^3 * y^2 * x
sage: F.value()
x^3*y^2*x
```

gcd (other)

Return the gcd of two factorizations.

If the two factorizations have different universes, this method will attempt to find a common universe for

the gcd. A TypeError is raised if this is impossible.

EXAMPLES:

```
sage: factor(-30).gcd(factor(-160))
2 * 5
sage: factor(gcd(-30,160))
2 * 5

sage: R.<x> = ZZ[]
sage: (factor(-20).gcd(factor(5*x+10))).universe()
Univariate Polynomial Ring in x over Integer Ring
```

is_commutative()

Return True if my factors commute.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.is_commutative()
True
sage: K = QuadraticField(23, 'a')
sage: F = K.factor(13)
sage: F.is_commutative()
True
sage: R.<x,y,z> = FreeAlgebra(QQ, 3)
sage: F = Factorization([(z, 2)], 3)
sage: F.is_commutative()
False
sage: (F*F^-1).is_commutative()
```

is_integral()

Return True iff all exponents of this Factorization are non-negative.

EXAMPLES:

```
sage: F = factor(-10); F
-1 * 2 * 5
sage: F.is_integral()
True

sage: F = factor(-10) / factor(16); F
-1 * 2^-3 * 5
sage: F.is_integral()
False
```

lcm (other)

Return the lcm of two factorizations.

If the two factorizations have different universes, this method will attempt to find a common universe for the lcm. A TypeError is raised if this is impossible.

```
sage: factor(-10).lcm(factor(-16))
2^4 * 5
sage: factor(lcm(-10,16))
2^4 * 5
sage: R.<x> = ZZ[]
sage: (factor(-20).lcm(factor(5*x+10))).universe()
```

```
Univariate Polynomial Ring in x over Integer Ring
```

prod()

Return the product of the factors in the factorization, multiplied out.

EXAMPLES:

```
sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.value()
-2006

sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (x,1)]); F
x^3 * y^2 * x
sage: F.value()
x^3*y^2*x
```

radical()

Return the factorization of the radical of the value of self.

First, check that all exponents in the factorization are positive, raise ValueError otherwise. If all exponents are positive, return self with all exponents set to 1 and with the unit set to 1.

EXAMPLES:

```
sage: F = factor(-100); F
-1 * 2^2 * 5^2
sage: F.radical()
2 * 5
sage: factor(1/2).radical()
Traceback (most recent call last):
...
ValueError: All exponents in the factorization must be positive.
```

radical_value()

Return the product of the prime factors in self.

First, check that all exponents in the factorization are positive, raise ValueError otherwise. If all exponents are positive, return the product of the prime factors in self. This should be functionally equivalent to self.radical().value()

EXAMPLES:

```
sage: F = factor(-100); F
-1 * 2^2 * 5^2
sage: F.radical_value()
10
sage: factor(1/2).radical_value()
Traceback (most recent call last):
...
ValueError: All exponents in the factorization must be positive.
```

simplify()

Combine adjacent products as much as possible.

TESTS:

```
sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (y,2)], simplify=False); F
x^3 * y^2 * y^2
```

```
sage: F.simplify(); F
x^3 * y^4
sage: F * Factorization([(y, -2)], 2)
(2) * x^3 * y^2
```

sort (_cmp=None)

Sort the factors in this factorization.

INPUT:

•_cmp - (default: None) comparison function

OUTPUT:

•changes this factorization to be sorted

If _cmp is None, we determine the comparison function as follows: If the prime in the first factor has a dimension method, then we sort based first on *dimension* then on the exponent. If there is no dimension method, we next attempt to sort based on a degree method, in which case, we sort based first on *degree*, then exponent to break ties when two factors have the same degree, and if those match break ties based on the actual prime itself. If there is no degree method, we sort based on dimension.

EXAMPLES:

We create a factored polynomial:

```
sage: x = polygen(QQ,'x')

sage: F = factor(x^3 + 1); F(x + 1) * (x^2 - x + 1)
```

Then we sort it but using the negated version of the standard Python cmp function:

```
sage: F.sort(_cmp = lambda x,y: -cmp(x,y))
sage: F
(x^2 - x + 1) * (x + 1)
```

unit()

Return the unit part of this factorization.

EXAMPLES:

We create a polynomial over the real double field and factor it:

```
sage: x = polygen(RDF, 'x')

sage: F = factor(-2*x^2 - 1); F(-2.0) * (x^2 + 0.5)
```

Note that the unit part of the factorization is -2.0:

```
sage: F.unit()
-2.0

sage: F = factor(-2006); F
-1 * 2 * 17 * 59

sage: F.unit()
-1
```

universe()

Return the parent structure of my factors.

Note: This used to be called base_ring, but the universe of a factorization need not be a ring.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.universe()
Integer Ring

sage: R.<x,y,z> = FreeAlgebra(QQ, 3)
sage: F = Factorization([(z, 2)], 3)
sage: (F*F^-1).universe()
Free Algebra on 3 generators (x, y, z) over Rational Field

sage: F = ModularSymbols(11,4).factorization()
sage: F.universe()
```

value()

Return the product of the factors in the factorization, multiplied out.

```
sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.value()
-2006

sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (x,1)]); F
x^3 * y^2 * x
sage: F.value()
x^3*y^2*x
```

CHAPTER

ELEMENTS

Elements

AUTHORS:

- David Harvey (2006-10-16): changed CommutativeAlgebraElement to derive from CommutativeRingElement instead of AlgebraElement
- David Harvey (2006-10-29): implementation and documentation of new arithmetic architecture
- William Stein (2006-11): arithmetic architecture pushing it through to completion.
- Gonzalo Tornaria (2007-06): recursive base extend for coercion lots of tests
- Robert Bradshaw (2007-2010): arithmetic operators and coercion
- Maarten Derickx (2010-07): added architecture for is_square and sqrt

9.1 The Abstract Element Class Hierarchy

This is the abstract class hierarchy, i.e., these are all abstract base classes.

MonoidElement

```
SageObject
    Element
        ModuleElement
            RingElement
                CommutativeRingElement
                    IntegralDomainElement
                        DedekindDomainElement
                            PrincipalIdealDomainElement
                                EuclideanDomainElement
                    FieldElement
                        FiniteFieldElement
                    CommutativeAlgebraElement
                AlgebraElement (note -- can't derive from module, since no multiple inheritance)
                    CommutativeAlgebra ??? (should be removed from element.pxd)
                    Matrix
                InfinityElement
                    PlusInfinityElement
                    MinusInfinityElement
            AdditiveGroupElement
            Vector
```

```
MultiplicativeGroupElement
ElementWithCachedMethod
```

9.2 How to Define a New Element Class

Elements typically define a method _new_c, e.g.,

```
cdef _new_c(self, defining data):
    cdef FreeModuleElement_generic_dense x
    x = PY_NEW(FreeModuleElement_generic_dense)
    x._parent = self._parent
    x._entries = v
```

that creates a new sibling very quickly from defining data with assumed properties.

Sage has a special system in place for handling arithmetic operations for all Element subclasses. There are various rules that must be followed by both arithmetic implementers and callers.

A quick summary for the impatient:

- To implement addition for any Element class, override def _add_().
- If you want to add x and y, whose parents you know are IDENTICAL, you may call _add_(x, y). This will be the fastest way to guarantee that the correct implementation gets called. Of course you can still always use "x + y".

Now in more detail. The aims of this system are to provide (1) an efficient calling protocol from both Python and Cython, (2) uniform coercion semantics across Sage, (3) ease of use, (4) readability of code.

We will take addition of RingElements as an example; all other operators and classes are similar. There are four relevant functions.

def RingElement.__add__

This function is called by Python or Pyrex when the binary "+" operator is encountered. It ASSUMES that at least one of its arguments is a RingElement; only a really twisted programmer would violate this condition. It has a fast pathway to deal with the most common case where the arguments have the same parent. Otherwise, it uses the coercion module to work out how to make them have the same parent. After any necessary coercions have been performed, it calls _add_ to dispatch to the correct underlying addition implementation.

Note that although this function is declared as def, it doesn't have the usual overheads associated with python functions (either for the caller or for __add__ itself). This is because python has optimised calling protocols for such special functions.

def RingElement. add

This is the function you should override to implement addition in a python subclass of RingElement.

Warning: if you override this in a *Cython* class, it won't get called. You should override _add_ instead. It is especially important to keep this in mind whenever you move a class down from Python to Cython.

The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

If you want to add two objects from python, and you know that their parents are the same object, you are encouraged to call this function directly, instead of using "x + y".

The default implementation of this function is to call _add_, so if no-one has defined a python implementation, the correct Pyrex implementation will get called.

cpdef RingElement._add_

This is the function you should override to implement addition in a Pyrex subclass of RingElement.

The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

The default implementation of this function is to raise a NotImplementedError, which will happen if no-one has supplied implementations of either _add_.

For speed, there are also **inplace** version of the arithmetic commands. DD NOT call them directly, they may mutate the object and will be called when and only when it has been determined that the old object will no longer be accessible from the calling function after this operation.

def RingElement._iadd_

This is the function you should override to inplace implement addition in a Python subclass of RingElement.

The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

The default implementation of this function is to call _add_, so if no-one has defined a Python implementation, the correct Cython implementation will get called.

```
class sage.structure.element.AdditiveGroupElement
    Bases: sage.structure.element.ModuleElement
    Generic element of an additive group.
    order()
         Return additive order of element
class sage.structure.element.AlgebraElement
    Bases: sage.structure.element.RingElement
    INPUT:
        •parent - a SageObject
class sage.structure.element.CoercionModel
    Bases: object
    Most basic coercion scheme. If it doesn't already match, throw an error.
    bin_op(x, y, op)
    canonical coercion (x, y)
class sage.structure.element.CommutativeAlgebra
    Bases: sage.structure.element.AlgebraElement
    INPUT:
        •parent - a SageObject
class sage.structure.element.CommutativeAlgebraElement
    Bases: sage.structure.element.CommutativeRingElement
    INPUT:
        •parent - a SageObject
```

```
class sage.structure.element.CommutativeRingElement
    Bases: sage.structure.element.RingElement
    Base class for elements of commutative rings.
    divides(x)
         Return True if self divides x.
         EXAMPLES:
         sage: P.<x> = PolynomialRing(QQ)
         sage: x.divides(x^2)
         sage: x.divides(x^2+2)
         False
         sage: (x^2+2).divides(x)
         sage: P.<x> = PolynomialRing(ZZ)
         sage: x.divides(x^2)
         True
         sage: x.divides(x^2+2)
         False
         sage: (x^2+2).divides(x)
         False
         Ticket #5347 has been fixed:
         sage: K = GF(7)
         sage: K(3).divides(1)
         True
         sage: K(3).divides(K(1))
         True
         sage: R = Integers(128)
         sage: R(0).divides(1)
         False
         sage: R(0).divides(0)
         True
         sage: R(0).divides(R(0))
         sage: R(1).divides(0)
         sage: R(121).divides(R(120))
         sage: R(120).divides(R(121))
         Traceback (most recent call last):
         ZeroDivisionError: reduction modulo right not defined.
```

If x has different parent than self, they are first coerced to a common parent if possible. If this coercion fails, it returns a TypeError. This fixes #5759

:: sage: Zmod(2)(0).divides(Zmod(2)(0)) True sage: Zmod(2)(0).divides(Zmod(2)(1)) False sage: Zmod(5)(1).divides(Zmod(2)(1)) Traceback (most recent call last): ... TypeError: no common canonical parent for objects with parents: 'Ring of integers modulo 5' and 'Ring of integers modulo 2' sage: Zmod(35)(4).divides(Zmod(7)(1)) True sage: Zmod(35)(7).divides(Zmod(7)(1)) False

$inverse_mod(I)$

Return an inverse of self modulo the ideal I, if defined, i.e., if I and self together generate the unit ideal.

```
is_square(root=False)
```

Returns whether or not ring element is a square. If the optional argument root is True, then also returns the square root (or None, if the it is not a square).

INPUT:

•root - whether or not to also return a square root (default: False)

OUTPUT:

- •bool whether or not a square
- •object (optional) an actual square root if found, and None otherwise.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: f = 12*(x+1)^2 * (x+3)^2
sage: f.is_square()
False
sage: f.is_square(root=True)
(False, None)
sage: h = f/3
sage: h.is_square()
True
sage: h.is_square(root=True)
(True, 2*x^2 + 8*x + 6)
```

This is the is_square implementation for general commutative ring elements. It's implementation is to raise a NotImplementedError. The function definition is here to show what functionality is expected and provide a general framework.

mod(I)

Return a representative for self modulo the ideal I (or the ideal generated by the elements of I if I is not an ideal.)

EXAMPLE: Integers Reduction of 5 modulo an ideal:

```
sage: n = 5
sage: n.mod(3*ZZ)
2
```

Reduction of 5 modulo the ideal generated by 3:

```
sage: n.mod(3)
2
```

Reduction of 5 modulo the ideal generated by 15 and 6, which is (3).

```
sage: n.mod([15,6])
2
```

EXAMPLE: Univariate polynomials

```
sage: R.<x> = PolynomialRing(QQ)
sage: f = x^3 + x + 1
sage: f.mod(x + 1)
-1
```

When little is implemented about a given ring, then mod may return simply return f. For example, reduction is not implemented for $\mathbf{Z}[x]$ yet. (TODO!)

```
sage: R.\langle x \rangle = PolynomialRing(ZZ) sage: f = x^3 + x + 1 sage: f.mod(x + 1) - 1
```

EXAMPLE: Multivariate polynomials We reduce a polynomial in two variables modulo a polynomial and an ideal:

```
sage: R.\langle x, y, z \rangle = \text{PolynomialRing}(QQ, 3)

sage: (x^2 + y^2 + z^2).\text{mod}(x+y+z)

2*y^2 + 2*y*z + 2*z^2
```

Notice above that x is eliminated. In the next example, both y and z are eliminated:

```
sage: (x^2 + y^2 + z^2).mod( (x - y, y - z) )
3*z^2
sage: f = (x^2 + y^2 + z^2)^2; f
x^4 + 2*x^2*y^2 + y^4 + 2*x^2*z^2 + 2*y^2*z^2 + z^4
sage: f.mod( (x - y, y - z) )
9*z^4
```

In this example y is eliminated:

```
sage: (x^2 + y^2 + z^2).mod((x^3, y - z))
x^2 + 2*z^2
```

sqrt (extend=True, all=False, name=None)

It computes the square root.

INPUT:

- •extend Whether to make a ring extension containing a square root if self is not a square (default: True)
- •all Whether to return a list of all square roots or just a square root (default: False)
- •name Required when extend=True and self is not a square. This will be the name of the generator extension.

OUTPUT:

- •if all=False it returns a square root. (throws an error if extend=False and self is not a square)
- •if all=True it returns a list of all the square roots (could be empty if extend=False and self is not a square)

ALGORITHM:

It uses is_square(root=true) for the hard part of the work, the rest is just wrapper code.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: (x^2).sqrt()
x
sage: f=x^2-4*x+4; f.sqrt(all=True)
[x - 2, -x + 2]
sage: sqrtx=x.sqrt(name="y"); sqrtx
y
sage: sqrtx^2
x
sage: x.sqrt(all=true, name="y")
[y, -y]
sage: x.sqrt(extend=False, all=True)
[]
sage: x.sqrt()
Traceback (most recent call last):
...
```

TypeError: Polynomial is not a square. You must specify the name of the square root when using

```
Traceback (most recent call last):
         ValueError: trying to take square root of non-square x with extend = False
         TESTS:
         sage: f = (x+3)^2; f.sqrt()
         x + 3
         sage: f = (x+3)^2; f.sqrt(all=True)
         [x + 3, -x - 3]
         sage: f = (x^2 - x + 3)^2; f.sqrt()
         x^2 - x + 3

         sage: (1/(x^2-1)).sqrt()
         Traceback (most recent call last):
         TypeError: Polynomial is not a square. You must specify the name of the square root when usi
         sage: (1/(x^2-3)).sqrt(extend=False)
         Traceback (most recent call last):
         ValueError: trying to take square root of non-square 1/(x^2 - 3) with extend = False
class sage.structure.element.DedekindDomainElement
    Bases: sage.structure.element.IntegralDomainElement
    INPUT:
        •parent - a SageObject
class sage.structure.element.Element
    Bases: sage.structure.sage_object.SageObject
    Generic element of a structure. All other types of elements (RingElement, ModuleElement, etc) derive from this
    type.
```

sage: x.sqrt(extend=False)

Subtypes must either call __init__() to set _parent, or may set _parent themselves if that would be more efficient.

```
N (prec=None, digits=None, algorithm=None)
```

Return a numerical approximation of x with at least prec bits of precision.

EXAMPLES:

```
sage: (2/3).n()
0.6666666666666667
sage: pi.n(digits=10)
3.141592654
sage: pi.n(prec=20) # 20 bits
3.1416
```

TESTS:

Check that trac ticket #14778 is fixed:

```
sage: (0).n(algorithm='foo')
0.0000000000000000
```

$base_extend(R)$

base_ring()

Returns the base ring of this element's parent (if that makes sense).

category()

is_zero()

Return True if self equals self.parent()(0). The default implementation is to fall back to 'not self.__nonzero__'.

Warning: Do not re-implement this method in your subclass but implement __nonzero__ instead.

n (prec=None, digits=None, algorithm=None)

Return a numerical approximation of x with at least prec bits of precision.

EXAMPLES:

```
sage: (2/3).n()
0.666666666666667
sage: pi.n(digits=10)
3.141592654
sage: pi.n(prec=20) # 20 bits
3.1416
```

TESTS:

Check that trac ticket #14778 is fixed:

```
sage: (0).n(algorithm='foo')
0.0000000000000000
```

numerical_approx (prec=None, digits=None, algorithm=None)

Return a numerical approximation of x with at least prec bits of precision.

```
sage: (2/3).n()
0.666666666666667
sage: pi.n(digits=10)
3.141592654
```

parent (x=None)

Returns parent of this element; or, if the optional argument x is supplied, the result of coercing x into the parent of this element.

```
subs (in_dict=None, **kwds)
```

Substitutes given generators with given values while not touching other generators. This is a generic wrapper around __call__. The syntax is meant to be compatible with the corresponding method for symbolic expressions.

INPUT:

- •in_dict (optional) dictionary of inputs
- •**kwds named parameters

OUTPUT:

•new object if substitution is possible, otherwise self.

EXAMPLES:

```
sage: x, y = PolynomialRing(ZZ,2,'xy').gens()
sage: f = x^2 + y + x^2*y^2 + 5
sage: f((5,y))
25*y^2 + y + 30
sage: f.subs({x:5})
25*y^2 + y + 30
sage: f.subs(x=5)
25*y^2 + y + 30
sage: (1/f).subs(x=5)
1/(25*y^2 + y + 30)
sage: (1/f).subs(x=5)
```

substitute (in_dict=None, **kwds)

This is an alias for self.subs().

INPUT:

- •in_dict (optional) dictionary of inputs
- •**kwds named parameters

OUTPUT:

•new object if substitution is possible, otherwise self.

```
sage: x, y = PolynomialRing(ZZ,2,'xy').gens()
sage: f = x^2 + y + x^2*y^2 + 5
sage: f((5,y))
25*y^2 + y + 30
sage: f.substitute({x:5})
```

```
25*y^2 + y + 30

sage: f.substitute(x=5)

25*y^2 + y + 30

sage: (1/f).substitute(x=5)

1/(25*y^2 + y + 30)

sage: Integer(5).substitute(x=4)

5
```

 ${\bf class}$ sage.structure.element.**ElementWithCachedMethod**

Bases: sage.structure.element.Element

An element class that fully supports cached methods.

NOTE:

The cached_method decorator provides a convenient way to automatically cache the result of a computation. Since trac ticket #11115, the cached method decorator applied to a method without optional arguments is faster than a hand-written cache in Python, and a cached method without any arguments (except self) is actually faster than a Python method that does nothing more but to return 1. A cached method can also be inherited from the parent or element class of a category.

However, this holds true only if attribute assignment is supported. If you write an extension class in Cython that does not accept attribute assignment then a cached method inherited from the category will be slower (for Parent) or the cache would even break (for Element).

This class should be used if you write an element class, can not provide it with attribute assignment, but want that it inherits a cached method from the category. Under these conditions, your class should inherit from this class rather than Element. Then, the cache will work, but certainly slower than with attribute assignment. Lazy attributes work as well.

EXAMPLE:

58

We define three element extension classes. The first inherits from Element, the second from this class, and the third simply is a Python class. We also define a parent class and, in Python, a category whose element and parent classes define cached methods.

```
sage: cython_code = ["from sage.structure.element cimport Element, ElementWithCachedMethod",
... "cdef class MyBrokenElement (Element):",
         cdef public object x",
. . .
         def __init__(self,P,x):",
             self.x=x",
             Element.__init__(self,P)",
         def __neg__(self):",
            return MyBrokenElement(self.parent(),-self.x)",
         def _repr_(self):",
            return '<%s>'%self.x",
         def __hash__(self):",
..."
            return hash(self.x)",
. . . "
         def __cmp__(left, right):",
..."
            return (<Element>left)._cmp(right)",
         def __richcmp__(left, right, op):",
. . .
             return (<Element>left)._richcmp(right,op)",
         cdef int _cmp_c_impl(left, Element right) except -2:",
             return cmp(left.x, right.x)",
         def raw_test(self):",
. . .
             return -self",
    "cdef class MyElement (ElementWithCachedMethod):",
         cdef public object x",
         def __init__(self,P,x):",
             self.x=x",
```

```
Element.__init__(self,P)",
        def __neg__(self):",
            return MyElement(self.parent(),-self.x)",
        def _repr_(self):",
            return '<%s>' %self.x",
        def __hash__(self):",
            return hash(self.x)",
        def __cmp__(left, right):",
           return (<Element>left)._cmp(right)",
        def __richcmp__(left, right, op):",
..."
           return (<Element>left)._richcmp(right,op)",
... "
        cdef int _cmp_c_impl(left, Element right) except -2:",
         return cmp(left.x,right.x)",
        def raw_test(self):",
            return -self",
... "class MyPythonElement(MyBrokenElement): pass",
... "from sage.structure.parent cimport Parent",
    'cdef class MyParent(Parent):",
        Element = MyElement"]
sage: cython('\n'.join(cython_code))
sage: cython_code = ["from sage.all import cached_method, cached_in_parent_method, Category, Obj
... "class MyCategory (Category):",
       @cached_method",
..."
        def super_categories(self):",
... "
         return [Objects()]",
..."
       class ElementMethods:",
           @cached method",
           def element_cache_test(self):",
              return -self",
           @cached_in_parent_method",
            def element_via_parent_test(self):",
                return -self",
        class ParentMethods:",
         @cached_method",
           def one(self):",
               return self.element_class(self,1)",
..."
           @cached_method",
..."
            def invert(self, x):",
                return -x"]
sage: cython('\n'.join(cython_code))
sage: C = MyCategory()
sage: P = MyParent(category=C)
sage: ebroken = MyBrokenElement(P,5)
sage: e = MyElement(P,5)
The cached methods inherited by MyElement works:
sage: e.element_cache_test()
<-5>
sage: e.element_cache_test() is e.element_cache_test()
True
sage: e.element_via_parent_test()
sage: e.element_via_parent_test() is e.element_via_parent_test()
```

The other element class can only inherit a cached_in_parent_method, since the cache is stored in the parent. In fact, equal elements share the cache, even if they are of different types:

True

sage: e == ebroken

```
True
     sage: type(e) == type(ebroken)
     sage: ebroken.element_via_parent_test() is e.element_via_parent_test()
     However, the cache of the other inherited method breaks, although the method as such works:
     sage: ebroken.element_cache_test()
     sage: ebroken.element_cache_test() is ebroken.element_cache_test()
     False
     Since e and ebroken share the cache, when we empty it for one element it is empty for the other as well:
     sage: b = ebroken.element_via_parent_test()
     sage: e.element_via_parent_test.clear_cache()
     sage: b is ebroken.element_via_parent_test()
     False
     Note that the cache only breaks for elements that do no allow attribute assignment. A Python version of
     MyBrokenElement therefore allows for cached methods:
     sage: epython = MyPythonElement(P,5)
     sage: epython.element_cache_test()
     <-5>
     sage: epython.element_cache_test() is epython.element_cache_test()
     True
class sage.structure.element.EuclideanDomainElement
     Bases: sage.structure.element.PrincipalIdealDomainElement
     INPUT:
        •parent - a SageObject
     degree()
     leading coefficient()
     quo_rem(other)
class sage.structure.element.FieldElement
     Bases: sage.structure.element.CommutativeRingElement
     INPUT:
        •parent - a SageObject
     divides (other)
         Check whether self divides other, for field elements.
         Since this is a field, all values divide all other values, except that zero does not divide any non-zero values.
         EXAMPLES:
         sage: K.<rt3> = QQ[sqrt(3)]
         sage: K(0).divides(rt3)
         False
         sage: rt3.divides(K(17))
         sage: K(0).divides(K(0))
```

```
True
         sage: rt3.divides(K(0))
         True
     is_unit()
         Return True if self is a unit in its parent ring.
         EXAMPLES:
         sage: a = 2/3; a.is_unit()
         True
         On the other hand, 2 is not a unit, since its parent is ZZ.
         sage: a = 2; a.is_unit()
         False
         sage: parent(a)
         Integer Ring
         However, a is a unit when viewed as an element of QQ:
         sage: a = QQ(2); a.is_unit()
         True
     quo_rem(right)
         Return the quotient and remainder obtained by dividing self by other. Since this element lives in a field,
         the remainder is always zero and the quotient is self/right.
         TESTS:
         Test if #8671 is fixed:
         sage: R. < x, y > = QQ[]
         sage: S.<a,b> = R.quo(y^2 + 1)
         sage: S.is_field = lambda : False
         sage: F = Frac(S); u = F.one_element()
         sage: u.quo_rem(u)
         (1, 0)
class sage.structure.element.InfinityElement
     Bases: sage.structure.element.RingElement
     INPUT:
        •parent - a SageObject
class sage.structure.element.IntegralDomainElement
     Bases: sage.structure.element.CommutativeRingElement
     INPUT:
        •parent - a SageObject
     is_nilpotent()
class sage.structure.element.Matrix
     Bases: sage.structure.element.ModuleElement
     INPUT:
        •parent - a SageObject
class sage.structure.element.MinusInfinityElement
     Bases: sage.structure.element.InfinityElement
```

```
INPUT:
         •parent - a SageObject
class sage.structure.element.ModuleElement
     Bases: sage.structure.element.Element
     Generic element of a module.
     additive order()
         Return the additive order of self.
     order()
         Return the additive order of self.
class sage.structure.element.MonoidElement
     Bases: sage.structure.element.Element
     Generic element of a monoid.
     multiplicative_order()
         Return the multiplicative order of self.
     order()
         Return the multiplicative order of self.
class sage.structure.element.MultiplicativeGroupElement
     Bases: sage.structure.element.MonoidElement
     Generic element of a multiplicative group.
     order()
         Return the multiplicative order of self.
class sage.structure.element.NamedBinopMethod
     Bases: object
     A decorator to be used on binary operation methods that should operate on elements of the same parent. If the
     parents of the arguments differ, coercion is performed, then the method is re-looked up by name on the first
     argument.
     In short, using the NamedBinopMethod (alias coerce_binop) decorator on a method gives it the exact
     same semantics of the basic arithmetic operations like add, sub, etc. in that both operands are guaranteed
     to have exactly the same parent.
class sage.structure.element.PlusInfinityElement
     Bases: sage.structure.element.InfinityElement
     INPUT:
         •parent - a SageObject
class sage.structure.element.PrincipalIdealDomainElement
     Bases: sage.structure.element.DedekindDomainElement
     INPUT:
         •parent - a SageObject
     lcm (right)
         Returns the least common multiple of self and right.
class sage.structure.element.RingElement
     Bases: sage.structure.element.ModuleElement
     INPUT:
```

62

```
abs()
          Return the absolute value of self. (This just calls the __abs__ method, so it is equivalent to the abs() built-in
          function.)
          EXAMPLES:
          sage: RR(-1).abs()
          1.000000000000000
          sage: ZZ(-1).abs()
          sage: CC(I).abs()
          1.000000000000000
          sage: Mod(-15, 37).abs()
          Traceback (most recent call last):
          ArithmeticError: absolute valued not defined on integers modulo n.
     additive_order()
          Return the additive order of self.
     is_nilpotent()
          Return True if self is nilpotent, i.e., some power of self is 0.
     is_one()
     multiplicative_order()
          Return the multiplicative order of self, if self is a unit, or raise ArithmeticError otherwise.
class sage.structure.element.Vector
     Bases: sage.structure.element.ModuleElement
     INPUT:
         •parent - a SageObject
sage.structure.element.bin_op (x, y, op)
sage.structure.element.canonical coercion (x, y)
     canonical_coercion(x,y) is what is called before doing an arithmetic operation between x and y. It returns a pair
     (z,w) such that z is got from x and w from y via canonical coercion and the parents of z and w are identical.
     EXAMPLES:
     sage: A = Matrix([[0,1],[1,0]])
     sage: canonical_coercion(A, 1)
     [0 1] [1 0]
     [1 0], [0 1]
sage.structure.element.coerce_binop
     alias of NamedBinopMethod
sage.structure.element.coerce_cmp (x, y)
sage.structure.element.coercion_traceback(dump=True)
     This function is very helpful in debugging coercion errors. It prints the tracebacks of all the errors caught in
     the coercion detection. Note that failure is cached, so some errors may be omitted the second time around (as it
```

For performance and caching reasons, exception recording must be explicitly enabled before using this function.

remembers not to retry failed paths for speed reasons.

•parent - a SageObject

```
EXAMPLES:
    sage: cm = sage.structure.element.get_coercion_model()
    sage: cm.record_exceptions()
    sage: 1 + 1/5
    6/5
    sage: coercion_traceback() # Should be empty, as all went well.
    sage: 1/5 + GF(5).gen()
    Traceback (most recent call last):
    TypeError: unsupported operand parent(s) for '+': 'Rational Field' and 'Finite Field of size 5'
    sage: coercion_traceback()
    Traceback (most recent call last):
    TypeError: no common canonical parent for objects with parents: 'Rational Field' and 'Finite Fie
sage.structure.element.gcd (x, y)
sage.structure.element.generic_power(a, n, one=None)
    Computes a^n, where n is an integer, and a is an object which supports multiplication. Optionally an additional
    argument, which is used in the case that n == 0:
        •one - the "unit" element, returned directly (can be anything)
    If this is not supplied, int(1) is returned.
    EXAMPLES:
    sage: from sage.structure.element import generic_power
    sage: generic_power(int(12),int(0))
    sage: generic_power(int(0),int(100))
    sage: generic_power(Integer(10), Integer(0))
    sage: generic_power(Integer(0), Integer(23))
    sage: sum([generic_power(2,i) for i in range(17)]) #test all 4-bit combinations
    131071
    sage: F = Zmod(5)
    sage: a = generic_power(F(2), 5); a
    sage: a.parent() is F
    True
    sage: a = generic_power(F(1), 2)
    sage: a.parent() is F
    True
    sage: generic_power(int(5), 0)
sage.structure.element.get_coercion_model()
    Return the global coercion model.
    EXAMPLES:
    sage: import sage.structure.element as e
    sage: cm = e.get_coercion_model()
    sage: cm
    <sage.structure.coerce.CoercionModel_cache_maps object at ...>
```

```
sage.structure.element.is AdditiveGroupElement(x)
    Return True if x is of type AdditiveGroupElement.
sage.structure.element.is_AlgebraElement(x)
    Return True if x is of type AlgebraElement.
sage.structure.element.is CommutativeAlgebraElement(x)
    Return True if x is of type CommutativeAlgebraElement.
sage.structure.element.is CommutativeRingElement(x)
    Return True if x is of type CommutativeRingElement.
sage.structure.element.is_DedekindDomainElement(x)
    Return True if x is of type DedekindDomainElement.
sage.structure.element.is_Element(x)
    Return True if x is of type Element.
    EXAMPLES:
    sage: from sage.structure.element import is_Element
    sage: is_Element(2/3)
    sage: is_Element(QQ^3)
    False
sage.structure.element.is_EuclideanDomainElement(x)
    Return True if x is of type EuclideanDomainElement.
sage.structure.element.is_FieldElement(x)
    Return True if x is of type FieldElement.
sage.structure.element.is_InfinityElement(x)
    Return True if x is of type InfinityElement.
sage.structure.element.is_IntegralDomainElement(x)
    Return True if x is of type IntegralDomainElement.
sage.structure.element.is_Matrix(x)
sage.structure.element.is_ModuleElement(x)
    Return True if x is of type ModuleElement.
    This is even faster than using isinstance inline.
    EXAMPLES:
    sage: from sage.structure.element import is_ModuleElement
    sage: is_ModuleElement(2/3)
    sage: is_ModuleElement((QQ^3).0)
    sage: is_ModuleElement('a')
    False
sage.structure.element.is_MonoidElement(x)
    Return True if x is of type MonoidElement.
sage.structure.element.is_MultiplicativeGroupElement(x)
    Return True if x is of type MultiplicativeGroupElement.
sage.structure.element.is_PrincipalIdealDomainElement(x)
    Return True if x is of type PrincipalIdealDomainElement.
```

```
sage.structure.element.is_RingElement(x)
    Return True if x is of type RingElement.
sage.structure.element.is_Vector(x)
sage.structure.element.lcm(x, y)
sage.structure.element.make_element(_class, _dict, parent)
    This function is only here to support old pickles.
    Pickling functionality is moved to Element.{__getstate___, _setstate__}} functions.
sage.structure.element.parent(x)
sage.structure.element.py_scalar_to_element(py)
sage.structure.element.set_coercion_model(cm)
sage.structure.element.xgcd(x, y)
```

UNIQUE REPRESENTATION

Abstract classes for cached and unique representation behavior.

See Also:

```
sage.structure.factory.UniqueFactory
```

AUTHORS:

- Nicolas M. Thiery (2008): Original version.
- Simon A. King (2013-02): Separate cached and unique representation.
- Simon A. King (2013-08): Extended documentation.

10.1 What is a cached representation?

Instances of a class have a *cached representation behavior* when several instances constructed with the same arguments share the same memory representation. For example, calling twice:

```
sage: G = SymmetricGroup(6)
sage: H = SymmetricGroup(6)
```

to create the symmetric group on six elements gives back the same object:

```
sage: G is H
True
```

This is a standard design pattern. Besides saving memory, it allows for sharing cached data (say representation theoretical information about a group). And of course a look-up in the cache is faster than the creation of a new object.

10.1.1 Implementing a cached representation

Sage provides two standard ways to create a cached representation: CachedRepresentation and UniqueFactory. Note that, in spite of its name, UniqueFactory does not ensure *unique* representation behaviour, which will be explained below.

Using CachedRepresentation

It is often very easy to use CachedRepresentation: One simply writes a Python class and adds CachedRepresentation to the list of base classes. If one does so, then the arguments used to create an instance of this class will by default also be used as keys for the cache:

```
sage: from sage.structure.unique_representation import CachedRepresentation
sage: class C(CachedRepresentation):
....:     def __init__(self, a, b=0):
....:         self.a = a
....:         self.b = b
....:     def __repr__(self):
....:         return "C(%s, %s)"%(self.a, self.b)
....:
sage: a = C(1)
sage: a is C(1)
True
```

In addition, pickling just works, provided that Python is able to look up the class. Hence, in the following two lines, we explicitly put the class into the main module. This is needed in doctests, but not in an interactive session:

```
sage: import __main__
sage: __main__.C = C
sage: loads(dumps(a)) is a
True
```

Often, this very easy approach is sufficient for applications. However, there are some pitfalls. Since the arguments are used for caching, all arguments must be hashable, i.e., must be valid as dictionary keys:

```
sage: C((1,2))
C((1, 2), 0)
sage: C([1,2])
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
```

In addition, equivalent ways of providing the arguments are *not* automatically normalised when forming the cache key, and hence different but equivalent arguments may yield distinct instances:

```
sage: C(1) is C(1,0)
False
sage: C(1) is C(a=1)
False
sage: repr(C(1)) == repr(C(a=1))
True
```

It should also be noted that the arguments are compared by equality, not by identity. This is often desired, but can imply subtle problems. For example, since $\mathbb{C}(1)$ already is in the cache, and since the unit elements in different finite fields are all equal to the integer one, we find:

```
sage: GF(5)(1) == 1 == GF(3)(1)
True
sage: C(1) is C(GF(3)(1)) is C(GF(5)(1))
True
```

But C(2) is not in the cache, and the number two is not equal in different finite fields (i. e., GF(5)(2) = GF(3)(2) returns as False), even though it is equal to the number two in the ring of integers (GF(5)(2) = 2 = GF(3)(2) returns as True; equality is not transitive when comparing elements of *distinct* algebraic structures!!). Hence, we have:

```
sage: GF(5)(2) == GF(3)(2)
False
sage: C(GF(3)(2)) is C(GF(5)(2))
False
```

Normalising the arguments

CachedRepresentation uses the metaclass ClasscallMetaclass. Its __classcall__ method is a WeakCachedFunction. This function creates an instance of the given class using the given arguments, unless it finds the result in the cache. This has the following implications:

- The arguments must be valid dictionary keys (i.e., they must be hashable; see above).
- It is a weak cache, hence, if the user does not keep a reference to the resulting instance, then it may be removed from the cache during garbage collection.
- It is possible to preprocess the input arguments by implementing a __classcall__ or a __classcall_private_ method, but in order to benefit from caching, CachedRepresentation.__classcall__() should at some point be called.

Note: For technical reasons, it is needed that __classcall__ respectively __classcall_private__ are "static methods", i.e., they are callable objects that do not bind to an instance or class. For example, a cached_function can be used here, because it is callable, but does not bind to an instance or class, because it has no __get__() method. A usual Python function, however, has a __get__() method and would thus under normal circumstances bind to an instance or class, and thus the instance or class would be passed to the function as the first argument. To prevent a callable object from being bound to the instance or class, one can prepend the @staticmethod decorator to the definition; see staticmethod.

For more on Python's __get__() method, see: http://docs.python.org/2/howto/descriptor.html

Warning: If there is preprocessing, then the preprocessed arguments passed to passed to CachedRepresentation.__classcall__() must be invariant under the preprocessing. That is to say, preprocessing the input arguments twice must have the same effect as preprocessing the input arguments only once. That is to say, the preprocessing must be idempotent.

The reason for this warning lies in the way pickling is implemented. If the preprocessed arguments are passed to CachedRepresentation.__classcall__(), then the resulting instance will store the *preprocessed* arguments in some attribute, and will use them for pickling. If the pickle is unpickled, then preprocessing is applied to the preprocessed arguments—and this second round of preprocessing must not change the arguments further, since otherwise a different instance would be created.

We illustrate the warning by an example. Imagine that one has instances that are created with an integer-valued argument, but only depend on the *square* of the argument. It would be a mistake to square the given argument during preprocessing:

```
sage: class WrongUsage(CachedRepresentation):
          @staticmethod
          def __classcall__(cls, n):
              return super (WrongUsage, cls).__classcall__(cls, n^2)
          def __init__(self, n):
. . . . :
              self.n = n
          def __repr__(self):
              return "Something(%d)"%self.n
. . . . :
sage: import __main_
sage: __main__.WrongUsage = WrongUsage # This is only needed in doctests
sage: w = WrongUsage(3); w
Something (9)
sage: w._reduction
(<class '__main__.WrongUsage'>, (9,), {})
```

Indeed, the reduction data are obtained from the preprocessed argument. By consequence, if the resulting instance is pickled and unpickled, the argument gets squared *again*:

```
sage: loads(dumps(w))
Something(81)
```

Instead, the preprocessing should only take the absolute value of the given argument, while the squaring should happen inside of the __init__ method, where it won't mess with the cache:

```
sage: class BetterUsage (CachedRepresentation):
         @staticmethod
. . . . :
          def __classcall__(cls, n):
. . . . :
              return super (BetterUsage, cls).__classcall__(cls, abs(n))
. . . . :
          def __init__(self, n):
. . . . :
              self.n = n^2
. . . . :
         def ___repr__(self):
. . . . :
              return "SomethingElse(%d)"%self.n
. . . . :
. . . . :
sage: __main__.BetterUsage = BetterUsage # This is only needed in doctests
sage: b = BetterUsage(3); b
SomethingElse(9)
sage: loads(dumps(b)) is b
sage: b is BetterUsage(-3)
True
```

In our next example, we create a cached representation class C that returns an instance of a sub-class C1 or C2 depending on the given arguments. This is implemented in a static __classcall_private__ method of C, letting it choose the sub-class according to the given arguments. Since a __classcall_private__ method will be ignored on sub-classes, the caching of CachedRepresentation is available to both C1 and C2. But for illustration, we overload the static __classcall__ method on C2, doing some argument preprocessing. We also create a sub-class C2b of C2, demonstrating that the __classcall__ method is used on the sub-class (in contrast to a __classcall_private__ method!).

```
sage: class C(CachedRepresentation):
. . . . :
          @staticmethod
          def __classcall_private__(cls, n, implementation=0):
. . . . :
               if not implementation:
                   return C.__classcall__(cls, n)
               if implementation==1:
. . . . :
                   return C1(n)
. . . . :
               if implementation>1:
. . . . :
                   return C2(n,implementation)
. . . . :
          def __init__(self, n):
. . . . :
              self.n = n
          def __repr__(self):
. . . . :
              return "C(%d, 0)"%self.n
. . . . :
sage: class C1(C):
         def ___repr__(self):
. . . . :
              return "C1(%d)"%self.n
. . . . :
sage: class C2(C):
         @staticmethod
. . . . :
          def __classcall__(cls, n, implementation=0):
. . . . :
              if implementation:
. . . . :
                   return super(C2, cls).__classcall__(cls, (n,)*implementation)
. . . . :
               return super(C2, cls).__classcall__(cls, n)
```

```
def __init__(self, t):
. . . . :
              self.t = t
. . . . :
          def __repr__(self):
. . . . :
               return "C2(%s)"%repr(self.t)
. . . . :
. . . . :
sage: class C2b(C2):
          def __repr__(self):
. . . . :
               return "C2b(%s)"%repr(self.t)
. . . . :
sage: __main__.C2 = C2
                               # not needed in an interactive session
sage: __main__.C2b = C2b
```

In the above example, C drops the argument implementation if it evaluates to False, and since the cached __classcall__ is called in this case, we have:

```
sage: C(1)
C(1, 0)
sage: C(1) is C(1,0)
True
sage: C(1) is C(1,0) is C(1,None) is C(1,[])
True
```

(Note that we were able to bypass the issue of arguments having to be hashable by catching the empty list [] during preprocessing in the __classcall_private__ method. Similarly, unhashable arguments can be made hashable - e. g., lists normalized to tuples - in the __classcall_private__ method before they are further delegated to __classcall__. See TCrystal for an example.)

If we call C1 directly or if we provide implementation=1 to C, we obtain an instance of C1. Since it uses the __classcall__ method inherited from CachedRepresentation, the resulting instances are cached:

```
sage: C1(2)
C1(2)
sage: C(2, implementation=1)
C1(2)
sage: C(2, implementation=1) is C1(2)
True
```

The class C2 preprocesses the input arguments. Instances can, again, be obtained directly or by calling C:

```
sage: C(1, implementation=3)
C2((1, 1, 1))
sage: C(1, implementation=3) is C2(1,3)
True
```

The argument preprocessing of C2 is inherited by C2b, since __classcall__ and not __classcall_private__ is used. Pickling works, since the preprocessing of arguments is idempotent:

```
sage: c2b = C2b(2,3); c2b
C2b((2, 2, 2))
sage: loads(dumps(c2b)) is c2b
True
```

Using UniqueFactory

For creating a cached representation using a factory, one has to

- create a class *separately* from the factory. This class **must** inherit from object. Its instances **must** allow attribute assignment.
- write a method create_key (or create_key_and_extra_args) that creates the cache key from the given arguments.
- write a method create_object that creates an instance of the class from a given cache key.
- · create an instance of the factory with a name that allows to conclude where it is defined.

An example:

```
sage: class C(object):
         def __init__(self, t):
. . . . :
              self.t = t
. . . . :
          def __repr__(self):
               return "C%s"%repr(self.t)
. . . . :
. . . . :
sage: from sage.structure.factory import UniqueFactory
sage: class MyFactory(UniqueFactory):
          def create_key(self, n, m=None):
              if isinstance(n, (tuple, list)) and m is None:
                   return tuple(n)
              return (n,) *m
         def create_object(self, version, key, **extra_args):
. . . . :
               # We ignore version and extra_args
. . . . :
               return C(key)
. . . . :
. . . . :
```

Now, we define an instance of the factory, stating that it can be found under the name "F" in the __main__ module. By consequence, pickling works:

```
sage: F = MyFactory("__main__.F")
sage: __main__.F = F  # not needed in an interactive session
sage: loads(dumps(F)) is F
True
```

We can now create *cached* instances of C by calling the factory. The cache only takes into account the key computed with the method <code>create_key</code> that we provided. Hence, different given arguments may result in the same instance. Note that, again, the cache is weak, hence, the instance might be removed from the cache during garbage collection, unless an external reference is preserved.

```
sage: a = F(1, 2); a
C(1, 1)
sage: a is F((1,1))
True
```

If the class of the returned instances is a sub-class of object, and if the resulting instance allows attribute assignment, then pickling of the resulting instances is automatically provided for, and respects the cache.

```
sage: loads(dumps(a)) is a
True
```

This is because an attribute is stored that explains how the instance was created:

```
sage: a._factory_data
(<class '__main__.MyFactory'>, (...), (1, 1), {})
```

Note: If a class is used that does not inherit from object then unique pickling is *not* provided.

Caching is only available if the factory is called. If an instance of the class is directly created, then the cache is not used:

```
sage: C((1,1))
C(1, 1)
sage: C((1,1)) is a
False
```

10.1.2 Comparing the two ways of implementing a cached representation

In this sub-section, we discuss advantages and disadvantages of the two ways of implementing a cached representation, depending on the type of application.

Simplicity and transparency

In many cases, turning a class into a cached representation requires nothing more than adding CachedRepresentation to the list of base classes of this class. This is, of course, a very easy and convenient way. Writing a factory would involve a lot more work.

If preprocessing of the arguments is needed, then we have seen how to do this by a __classcall_private__ or __classcall_method. But these are double underscore methods and hence, for example, invisible in the automatically created reference manual. Moreover, preprocessing *and* caching are implemented in the same method, which might be confusing. In a unique factory, these two tasks are cleanly implemented in two separate methods. With a factory, it is possible to create the resulting instance by arguments that are different from the key used for caching. This is significantly restricted with CachedRepresentation due to the requirement that argument preprocessing be idempotent.

Hence, if advanced preprocessing is needed, then UniqueFactory might be easier and more transparent to use than CachedRepresentation.

Class inheritance

Using CachedRepresentation has the advantage that one has a class and creates cached instances of this class by the usual Python syntax:

```
sage: G = SymmetricGroup(6)
sage: issubclass(SymmetricGroup, sage.structure.unique_representation.CachedRepresentation)
True
sage: isinstance(G, SymmetricGroup)
True
```

In contrast, a factory is just a callable object that returns something that has absolutely nothing to do with the factory, and may in fact return instances of quite different classes:

```
sage: isinstance(GF, sage.structure.factory.UniqueFactory)
True
sage: K5 = GF(5)
sage: type(K5)
<class 'sage.rings.finite_rings.finite_field_prime_modn.FiniteField_prime_modn_with_category'>
sage: K25 = GF(25, 'x')
sage: type(K25)
<class 'sage.rings.finite_rings.finite_field_givaro.FiniteField_givaro_with_category'>
sage: Kp = GF(next_prime_power(1000000)^2, 'x')
```

```
sage: type(Kp)
<class 'sage.rings.finite_rings.finite_field_pari_ffelt.FiniteField_pari_ffelt_with_category'>
```

This can be confusing to the user. Namely, the user might determine the class of an instance and try to create further instances by calling the class rather than the factory—which is a mistake since it works around the cache (and also since the class might be more restrictive than the factory—i. e., the type of K5 in the above doctest cannot be called on a prime power which is not a prime). This mistake can more easily be avoided by using CachedRepresentation.

We have seen above that one can easily create new cached-representation classes by subclassing an existing cached-representation class, even making use of an existing argument preprocess. This would be much more complicated with a factory. Namely, one would need to rewrite old factories making them aware of the new classes, and/or write new factories for the new classes.

Python versus extension classes

CachedRepresentation uses a metaclass, namely ClasscallMetaclass. Hence, it can currently not be a Cython extension class. Moreover, it is supposed to be used by providing it as a base class. But in typical applications, one also has another base class, say, Parent. Hence, one would like to create a class with at least two base classes, which is currently impossible in Cython extension classes.

In other words, when using CachedRepresentation, one must work with Python classes. These can be defined in Cython code (.pyx files) and can thus benefit from Cython's speed inside of their methods, but they must not be cdef class and can thus not use cdef attributes or methods.

Such restrictions do not exist when using a factory. However, if attribute assignment does not work, then the automatic pickling provided by UniqueFactory will not be available.

10.2 What is a unique representation?

Instances of a class have a *unique instance behavior* when instances of this class evaluate equal if and only if they are identical. Sage provides the base class WithEqualityById, which provides comparison by identity and a hash that is determined by the memory address of the instance. Both the equality test and the hash are implemented in Cython and are very fast, even when one has a Python class inheriting from WithEqualityById.

In many applications, one wants to combine unique instance and cached representation behaviour. This is called *unique representation* behaviour. We have seen above that symmetric groups have a *cached* representation behaviour. However, they do not show the *unique* representation behaviour, since they are equal to groups created in a totally different way, namely to subgroups:

```
sage: G = SymmetricGroup(6)
sage: G3 = G.subgroup([G((1,2,3,4,5,6)),G((1,2))])
sage: G is G3
False
sage: type(G) == type(G3)
False
sage: G == G3
```

The unique representation behaviour can conveniently be implemented with a class that inherits from UniqueRepresentation: By adding UniqueRepresentation to the base classes, the class will simultaneously inherit from CachedRepresentation and from WithEqualityById.

For example, a symmetric function algebra is uniquely determined by the base ring. Thus, it is reasonable to use UniqueRepresentation in this case:

```
sage: isinstance(SymmetricFunctions(CC), SymmetricFunctions)
True
sage: issubclass(SymmetricFunctions, UniqueRepresentation)
True
```

UniqueRepresentation differs from CachedRepresentation only by adding WithEqualityById as a base class. Hence, the above examples of argument preprocessing work for UniqueRepresentation as well.

Note that a cached representation created with UniqueFactory does *not* automatically provide unique representation behaviour, in spite of its name! Hence, for unique representation behaviour, one has to implement hash and equality test accordingly, for example by inheriting from WithEqualityById.

```
class sage.structure.unique_representation.CachedRepresentation
    Bases: object
```

Classes derived from CachedRepresentation inherit a weak cache for their instances.

Note: If this class is used as a base class, then instances are (weakly) cached, according to the arguments used to create the instance. Pickling is provided, of course by using the cache.

Note: Using this class, one can have arbitrary hash and comparison. Hence, *unique* representation behaviour is *not* provided.

See Also:

UniqueRepresentation, unique_representation

EXAMPLES:

Providing a class with a weak cache for the instances is easy: Just inherit from CachedRepresentation:

We start with a simple class whose constructor takes a single value as argument (TODO: find a more meaningful example):

```
sage: class MyClass(CachedRepresentation):
....:     def __init__(self, value):
....:         self.value = value
....:     def __cmp__(self, other):
....:         c = cmp(type(self), type(other))
...:         if c: return c
....:         return cmp(self.value, other.value)
```

Two coexisting instances of MyClass created with the same argument data are guaranteed to share the same identity. Since trac ticket #12215, this is only the case if there is some strong reference to the returned instance, since otherwise it may be garbage collected:

```
sage: x = MyClass(1)
sage: y = MyClass(1)
sage: x is y # There is a strong reference
True
sage: z = MyClass(2)
sage: x is z
False
```

In particular, modifying any one of them modifies the other (reference effect):

```
sage: x.value = 3
sage: x.value, y.value
(3, 3)
sage: y.value = 1
sage: x.value, y.value
(1, 1)
```

The arguments can consist of any combination of positional or keyword arguments, as taken by a usual __init__ function. However, all values passed in should be hashable:

```
sage: MyClass(value = [1,2,3])
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
```

Argument preprocessing

Sometimes, one wants to do some preprocessing on the arguments, to put them in some canonical form. The following example illustrates how to achieve this; it takes as argument any iterable, and canonicalizes it into a tuple (which is hashable!):

```
sage: class MyClass2 (CachedRepresentation):
         @staticmethod
. . . . :
         def __classcall__(cls, iterable):
             t = tuple(iterable)
. . . . :
              return super(MyClass2, cls).__classcall__(cls, t)
. . . . :
. . . . :
        def __init__(self, value):
. . . . :
             self.value = value
sage: x = MyClass2([1,2,3])
sage: y = MyClass2(tuple([1,2,3]))
sage: z = MyClass2(i for i in [1,2,3])
sage: x.value
(1, 2, 3)
sage: x is y, y is z
(True, True)
```

A similar situation arises when the constructor accepts default values for some of its parameters. Alas, the obvious implementation does not work:

```
sage: class MyClass3(CachedRepresentation):
....:     def __init__(self, value = 3):
....:         self.value = value
....:
sage: MyClass3(3) is MyClass3()
False
```

Instead, one should do:

```
sage: class MyClass3(UniqueRepresentation):
...:     @staticmethod
...:     def __classcall__(cls, value = 3):
...:         return super(MyClass3, cls).__classcall__(cls, value)
...:
def __init__(self, value):
...:     self.value = value
```

```
sage: MyClass3(3) is MyClass3()
True
```

A bit of explanation is in order. First, the call MyClass2([1,2,3]) triggers a call to MyClass2.__classcall__(MyClass2, [1,2,3]). This is an extension of the standard Python behavior, needed by CachedRepresentation, and implemented by the ClasscallMetaclass. Then, MyClass2.__classcall__ does the desired transformations on the arguments. Finally, it uses super to call the default implementation of __classcall__ provided by CachedRepresentation. This one in turn handles the caching and, if needed, constructs and initializes a new object in the class using __new__ and init as usual.

Constraints:

- •__classcall__() is a staticmethod (like, implicitly, __new__)
- •the preprocessing on the arguments should be idempotent. That is, if
 MyClass2.__classcall__(<arguments>) calls CachedRepresentation.__classcall__(preprocesten MyClass2.__classcall__(preprocessed_arguments>) should also result in a call
 to CachedRepresentation.__classcall__(preprocessed_arguments>).
- •MyClass2.__classcall__ should return the result of CachedRepresentation.__classcall__() without modifying it.

Other than that MyClass2.__classcall__ may play any tricks, like acting as a factory and returning objects from other classes.

Warning: It is possible, but strongly discouraged, to let the __classcall__ method of a class C return objects that are not instances of C. Of course, instances of a *subclass* of C are fine. Compare the examples in unique_representation.

We illustrate what is meant by an "idempotent" preprocessing. Imagine that one has instances that are created with an integer-valued argument, but only depend on the *square* of the argument. It would be a mistake to square the given argument during preprocessing:

```
sage: class WrongUsage (CachedRepresentation):
. . . . :
          @staticmethod
          def __classcall__(cls, n):
              return super (WrongUsage, cls).__classcall__(cls, n^2)
          def __init__(self, n):
              self.n = n
          def __repr__(self):
. . . . :
              return "Something(%d)"%self.n
sage: import __main_
sage: __main__.WrongUsage = WrongUsage # This is only needed in doctests
sage: w = WrongUsage(3); w
Something (9)
sage: w._reduction
(<class '__main__.WrongUsage'>, (9,), {})
```

Indeed, the reduction data are obtained from the preprocessed arguments. By consequence, if the resulting instance is pickled and unpickled, the argument gets squared *again*:

```
sage: loads(dumps(w))
Something(81)
```

Instead, the preprocessing should only take the absolute value of the given argument, while the squaring should happen inside of the __init__ method, where it won't mess with the cache:

```
sage: class BetterUsage (CachedRepresentation):
....: @staticmethod
         def __classcall__(cls, n):
. . . . :
              return super(BetterUsage, cls).__classcall__(cls, abs(n))
. . . . :
         def __init__(self, n):
              self.n = n^2
. . . . :
         def __repr__(self):
. . . . :
              return "SomethingElse(%d)"%self.n
. . . . :
sage: __main__.BetterUsage = BetterUsage # This is only needed in doctests
sage: b = BetterUsage(3); b
SomethingElse(9)
sage: loads(dumps(b)) is b
True
sage: b is BetterUsage(-3)
True
```

Cached representation and mutability

CachedRepresentation is primarily intended for implementing objects which are (at least semantically) immutable. This is in particular assumed by the default implementations of copy and deepcopy:

```
sage: copy(x) is x
True
sage: from copy import deepcopy
sage: deepcopy(x) is x
True
```

However, in contrast to UniqueRepresentation, using CachedRepresentation allows for a comparison that is not by identity:

```
sage: t = MyClass(3)
sage: z = MyClass(2)
sage: t.value = 2
```

Now t and z are non-identical, but equal:

```
sage: t.value == z.value
True
sage: t == z
True
sage: t is z
False
```

More on cached representation and identity

CachedRepresentation is implemented by means of a cache. This cache uses weak references. Hence, when all other references to, say, MyClass(1) have been deleted, the instance is actually deleted from memory. A later call to MyClass(1) reconstructs the instance from scratch.

```
sage: class SomeClass(UniqueRepresentation):
....:     def __init__(self, i):
....:         print "creating new instance for argument %s"%i
....:         self.i = i
....:         def __del__(self):
....:         print "deleting instance for argument %s"%self.i
```

```
sage: 0 = SomeClass(1)
creating new instance for argument 1
sage: 0 is SomeClass(1)
True
sage: 0 is SomeClass(2)
creating new instance for argument 2
deleting instance for argument 2
False
sage: del 0
deleting instance for argument 1
sage: 0 = SomeClass(1)
creating new instance for argument 1
sage: del 0
deleting instance for argument 1
sage: del 0
```

Cached representation and pickling

The default Python pickling implementation (by reconstructing an object from its class and dictionary, see "The pickle protocol" in the Python Library Reference) does not preserve cached representation, as Python has no chance to know whether and where the same object already exists.

CachedRepresentation tries to ensure appropriate pickling by implementing a __reduce__ method returning the arguments passed to the constructor:

```
sage: import __main__  # Fake MyClass being defined in a python module
sage: __main__.MyClass = MyClass
sage: x = MyClass(1)
sage: loads(dumps(x)) is x
```

CachedRepresentation uses the __reduce__ pickle protocol rather than __getnewargs__ because the latter does not handle keyword arguments:

```
sage: x = MyClass(value = 1)
sage: x.__reduce__()
(<function unreduce at ...>, (<class '__main__.MyClass'>, (), {'value': 1}))
sage: x is loads(dumps(x))
True
```

Note: The default implementation of <u>__reduce__</u> in CachedRepresentation requires to store the constructor's arguments in the instance dictionary upon construction:

```
sage: x.__dict__
{'_reduction': (<class '__main__.MyClass'>, (), {'value': 1}), 'value': 1}
```

It is often easy in a derived subclass to reconstruct the constructor's arguments from the instance data structure. When this is the case, __reduce__ should be overridden; automagically the arguments won't be stored anymore:

```
sage: class MyClass3 (UniqueRepresentation):
...:     def __init__(self, value):
...:         self.value = value
...:
...:     def __reduce__(self):
...:         return (MyClass3, (self.value,))
...:
```

```
sage: import __main__; __main__.MyClass3 = MyClass3 # Fake MyClass3 being defined in a python m
sage: x = MyClass3(1)
sage: loads(dumps(x)) is x
True
sage: x.__dict__
{'value': 1}
```

Migrating classes to CachedRepresentation and unpickling

We check that, when migrating a class to CachedRepresentation, older pickles can still be reasonably unpickled. Let us create a (new style) class, and pickle one of its instances:

```
sage: class MyClass4 (object):
....:     def __init__ (self, value):
....:          self.value = value
....:
sage: import __main__; __main__.MyClass4 = MyClass4 # Fake MyClass4 being defined in a python mage: pickle = dumps (MyClass4 (1))
It can be unpickled:
sage: y = loads (pickle)
```

```
sage: y - loads(pickle)
sage: y.value
1
```

Now, we upgrade the class to derive from UniqueRepresentation, which inherits from CachedRepresentation:

The pickle can still be unpickled:

```
sage: y = loads(pickle)
sage: y.value
1
```

Note however that, for the reasons explained above, unique representation is not guaranteed in this case:

```
sage: y is MyClass4(1)
False
```

Todo

Illustrate how this can be fixed on a case by case basis.

Now, we redo the same test for a class deriving from SageObject:

```
sage: class MyClass4 (SageObject):
....:     def __init__ (self, value):
....:          self.value = value
sage: import __main__; __main__.MyClass4 = MyClass4 # Fake MyClass4 being defined in a python m
sage: pickle = dumps (MyClass4 (1))
```

Caveat: unpickling instances of a formerly old-style class is not supported yet by default:

```
sage: class MyClass4:
....:     def __init__(self, value):
....:          self.value = value
sage: import __main__; __main__.MyClass4 = MyClass4  # Fake MyClass4 being defined in a python m
sage: pickle = dumps(MyClass4(1))

sage: class MyClass4 (UniqueRepresentation, SageObject):
....:          def __init__(self, value):
....:          self.value = value
sage: __main__.MyClass4 = MyClass4
sage: y = loads(pickle)  # todo: not implemented
sage: y.value  # todo: not implemented
```

Rationale for the current implementation

CachedRepresentation and derived classes use the ClasscallMetaclass of the standard Python type. The following example explains why.

We define a variant of MyClass where the calls to __init__ are traced:

```
sage: class MyClass(CachedRepresentation):
....:     def __init__(self, value):
....:          print "initializing object"
....:          self.value = value
....:
```

Let us create an object twice:

```
sage: x = MyClass(1)
initializing object
sage: z = MyClass(1)
```

As desired the __init__ method was only called the first time, which is an important feature.

As far as we can tell, this is not achievable while just using __new__ and __init__ (as defined by type; see Section Basic Customization in the Python Reference Manual). Indeed, __init__ is called systematically on the result of __new__ whenever the result is an instance of the class.

Another difficulty is that argument preprocessing (as in the example above) cannot be handled by __new__, since the unprocessed arguments will be passed down to __init__.

```
class sage.structure.unique_representation.UniqueRepresentation
```

```
Bases: sage.structure.unique_representation.CachedRepresentation, sage.misc.fast_methods.WithEqualityById
```

Classes derived from UniqueRepresentation inherit a unique representation behavior for their instances.

See Also:

```
unique_representation
```

EXAMPLES:

The short story: to construct a class whose instances have a unique representation behavior one just has to do:

Everything below is for the curious or for advanced usage.

What is unique representation?

Instances of a class have a *unique representation behavior* when instances evaluate equal if and only if they are identical (i.e., share the same memory representation), if and only if they were created using equal arguments. For example, calling twice:

```
sage: f = SymmetricFunctions(QQ)
sage: g = SymmetricFunctions(QQ)
```

to create the symmetric function algebra over **Q** actually gives back the same object:

```
sage: f == g
True
sage: f is g
True
```

This is a standard design pattern. It allows for sharing cached data (say representation theoretical information about a group) as well as for very fast hashing and equality testing. This behaviour is typically desirable for parents and categories. It can also be useful for intensive computations where one wants to cache all the operations on a small set of elements (say the multiplication table of a small group), and access this cache as quickly as possible.

UniqueRepresentation is very easy to use: a class just needs to derive from it, or make sure some of its super classes does. Also, it groups together the class and the factory in a single gadget:

```
sage: isinstance(SymmetricFunctions(CC), SymmetricFunctions)
True
sage: issubclass(SymmetricFunctions, UniqueRepresentation)
True
```

This nice behaviour is not available when one just uses a factory:

```
sage: isinstance(GF(7), GF)
Traceback (most recent call last):
...
TypeError: isinstance() arg 2 must be a class, type, or tuple of classes and types
sage: isinstance(GF, sage.structure.factory.UniqueFactory)
True
```

In addition, UniqueFactory only provides the *cached* representation behaviour, but not the *unique* representation behaviour—the examples in $unique_representation$ explain this difference.

On the other hand, the UniqueRepresentation class is more intrusive, as it imposes a behavior (and a metaclass) on all the subclasses. In particular, the unique representation behaviour is imposed on *all* subclasses (unless the __classcall__ method is overloaded and not called in the subclass, which is not recommended). Its implementation is also more technical, which leads to some subtleties.

We start with a simple class whose constructor takes a single value as argument. This pattern is similar to what is done in sage.combinat.sf.sf.SymmetricFunctions:

```
sage: class MyClass(UniqueRepresentation):
           def __init__(self, value):
. . . . :
               self.value = value
. . . . :
           def __cmp__(self, other):
. . . . :
               c = cmp(type(self), type(other))
. . . . :
               if c: return c
. . . . :
              print "custom cmp"
. . . . :
               return cmp(self.value, other.value)
. . . . :
. . . . :
```

Two coexisting instances of MyClass created with the same argument data are guaranteed to share the same identity. Since trac ticket #12215, this is only the case if there is some strong reference to the returned instance, since otherwise it may be garbage collected:

```
sage: x = MyClass(1)
sage: y = MyClass(1)
sage: x is y # There is a strong reference
True
sage: z = MyClass(2)
sage: x is z
False
```

In particular, modifying any one of them modifies the other (reference effect):

```
sage: x.value = 3
sage: x.value, y.value
(3, 3)
sage: y.value = 1
sage: x.value, y.value
(1, 1)
```

Rich comparison by identity is used when possible (hence, for ==, for !=, and for identical arguments in the case of <, <=, >= and >), which is as fast as it can get. Only if identity is not enough to decide the answer of a comparison, the custom comparison is called:

```
sage: x == y
True
sage: z = MyClass(2)
sage: x == z, x is z
(False, False)
sage: x <= x
True
sage: x != z
True
sage: x <= z
custom cmp
True
sage: x > z
custom cmp
False
```

A hash function equivalent to <code>object.__hash__()</code> is used, which is compatible with comparison by identity. However this means that the hash function may change in between Sage sessions, or even within the same Sage session.

```
sage: hash(x) == object.__hash__(x)
True
```

Warning: It is possible to inherit from UniqueRepresentation and then overload comparison in a way that destroys the unique representation property. We strongly recommend against it! You should use CachedRepresentation instead.

Mixing super types and super classes

TESTS:

For the record, this test did fail with previous implementation attempts:

```
sage: class bla(UniqueRepresentation, SageObject):
    ....:    pass
    ....:
    sage: b = bla()

sage.structure.unique_representation.unreduce(cls, args, keywords)
    Calls a class on the given arguments:
    sage: sage.structure.unique_representation.unreduce(Integer, (1,), {})
1
```

Todo

should reuse something preexisting ...

FACTORY FOR CACHED REPRESENTATIONS

Factory for cached representations

See Also:

sage.structure.unique representation

Using a UniqueFactory is one way of implementing a *cached representation behaviour*. In spite of its name, using a UniqueFactory is not enough to ensure the *unique representation behaviour*. See unique_representation for a detailed explanation.

With a UniqueFactory, one can preprocess the given arguments. There is special support for specifying a subset of the arguments that serve as the unique key, so that still *all* given arguments are used to create a new instance, but only the specified subset is used to look up in the cache. Typically, this is used to construct objects that accept an optional check=[True|False] argument, but whose result should be unique regardless of said optional argument. (This use case should be handled with care, though: Any checking which isn't done in the create_key or create_key_and_extra_args method will be done only when a new object is generated, but not when a cached object is retrieved from cache. Consequently, if the factory is once called with check=False, a subsequent call with check=True cannot be expected to perform all checks unless these checks are all in the create_key or create_key_and_extra_args method.)

For a class derived from CachedRepresentation, argument preprocessing can be obtained by providing a custom static __classcall__or __classcall_private__ method, but this seems less transparent. When argument preprocessing is not needed or the preprocess is not very sophisticated, then generally CachedRepresentation is much easier to use than a factory.

AUTHORS:

class sage.structure.factory.UniqueFactory

Bases: sage.structure.sage_object.SageObject

This class is intended to make it easy to cache objects.

It is based on the idea that the object is uniquely defined by a set of defining data (the key). There is also the possibility of some non-defining data (extra args) which will be used in initial creation, but not affect the caching. Warning: This class only provides *cached representation behaviour*. Hence, using UniqueFactory, it is still possible to create distinct objects that evaluate equal. Unique representation behaviour can be added, for example, by additionally inheriting from sage.misc.fast_methods.WithEqualityById.

The objects created are cached (using weakrefs) based on their key and returned directly rather than re-created if requested again. Pickling is taken care of by the factory, and will return the same object for the same version of Sage, and distinct (but hopefully equal) objects for different versions of Sage.

Warning: The objects returned by a UniqueFactory must be instances of new style classes (hence, they must be instances of object) that must not only allow a weak reference, but must accept general attribute assignment. Otherwise, pickling won't work.

USAGE:

A *unique factory* provides a way to create objects from parameters (the type of these objects can depend on the parameters, and is often determined only at runtime) and to cache them by a certain key derived from these parameters, so that when the factory is being called again with the same parameters (or just with parameters which yield the same key), the object is being returned from cache rather than constructed anew.

An implementation of a unique factory consists of a factory class and an instance of this factory class.

The factory class has to be a class inheriting from UniqueFactory. Typically it only needs to implement create_key() (a method that creates a key from the given parameters, under which key the object will be stored in the cache) and create_object() (a method that returns the actual object from the key). Sometimes, one would also implement create_key_and_extra_args() (this differs from create_key() in allowing to also create some additional arguments from the given parameters, which arguments then get passed to create_object() and thus can have an effect on the initial creation of the object, but do not affect the key) or other_keys(). Other methods are not supposed to be overloaded.

The factory class itself cannot be called to create objects. Instead, an instance of the factory class has to be created first. For technical reasons, this instance has to be provided with a name that allows Sage to find its definition. Specifically, the name of the factory instance (or the full path to it, if it is not in the global namespace) has to be passed to the factory class as a string variable. So, if our factory class has been called A and is located in sage/spam/battletoads.py, then we need to define an instance (say, B) of A by writing B = A("sage.spam.battletoads.B") (or B = A("B") if this B will be imported into global namespace). This instance can then be used to create objects (by calling B(*parameters)).

Notice that the objects created by the factory don't inherit from the factory class. They *do* know about the factory that created them (this information, along with the keys under which this factory caches them, is stored in the _factory_data attributes of the objects), but not via inheritance.

EXAMPLES:

The below examples are rather artificial and illustrate particular aspects. For a "real-life" usage case of UniqueFactory, see the finite field factory in sage.rings.finite_rings.constructor.

In many cases, a factory class is implemented by providing the two methods <code>create_key()</code> and <code>create_object()</code>. In our example, we want to demonstrate how to use "extra arguments" to choose a specific implementation, with preference given to an instance found in the cache, even if its implementation is different. Hence, we implement <code>create_key_and_extra_args()</code> rather than <code>create_key()</code>, putting the chosen implementation into the extra arguments. Then, in the <code>create_object()</code> method, we create and return instances of the specified implementation.

```
impl = extra_args['impl']
if impl=='C':
    return C(*key)
if impl=='D':
    return D(*key)
return E(*key)
```

Now we can create a factory instance. It is supposed to be found under the name "F" in the "__main__" module. Note that in an interactive session, F would automatically be in the __main__ module. Hence, the second and third of the following four lines are only needed in doctests.

```
sage: F = MyFactory("__main__.F")
sage: import __main__
sage: __main__.F = F
sage: loads(dumps(F)) is F
True
```

Now we create three classes C, D and E. The first is a Cython extension-type class that does not allow weak references nor attribute assignment. The second is a Python class that is not derived from object. The third allows attribute assignment and is derived from object.

```
sage: cython("cdef class C: pass")
sage: class D:
....:    def __init__(self, *args):
....:         self.t = args
....:    def __repr__(self):
....:         return "D%s"%repr(self.t)
....:
sage: class E(D, object): pass
```

Again, being in a doctest, we need to put the class D into the __main__ module, so that Python can find it:

```
sage: import __main__
sage: __main__.D = D
```

It is impossible to create an instance of C with our factory, since it does not allow weak references:

```
sage: F(1, impl='C')
Traceback (most recent call last):
...
TypeError: cannot create weak reference to '....C' object
```

Let us try again, with a Cython class that does allow weak references. Now, creation of an instance using the factory works:

The cache is used when calling the factory again—even if it is suggested to use a different implementation. This is because the implementation is only considered an "extra argument" that does not count for the key.

```
sage: c is F(1, impl='C') is F(1, impl="D") is F(1)
True
```

However, pickling and unpickling does not use the cache. This is because the factory has tried to assign an attribute to the instance that provides information on the key used to create the instance, but failed:

```
sage: loads(dumps(c)) is c
False
sage: hasattr(c, '_factory_data')
False
```

We have already seen that our factory will only take the requested implementation into account if the arguments used as key have not been used yet. So, we use other arguments to create an instance of class D:

```
sage: d = F(2, impl='D')
sage: isinstance(d, D)
True
```

The factory only knows about the pickling protocol used by new style classes. Hence, again, pickling and unpickling fails to use the cache, even though the "factory data" are now available:

```
sage: loads(dumps(d)) is d
False
sage: d._factory_data
(<class '__main__.MyFactory'>, (...), (2,), {'impl': 'D'})
```

Only when we have a new style class that can be weak referenced and allows for attribute assignment, everything works:

```
sage: e = F(3)
sage: isinstance(e, E)
True
sage: loads(dumps(e)) is e
True
sage: e._factory_data
(<class '__main__.MyFactory'>, (...), (3,), {'impl': None})
```

create_key (*args, **kwds)

Given the parameters (arguments and keywords), create a key that uniquely determines this object.

EXAMPLES:

```
sage: from sage.structure.test_factory import test_factory
sage: test_factory.create_key(1, 2, key=5)
(1, 2)
```

create_key_and_extra_args (*args, **kwds)

Return a tuple containing the key (uniquely defining data) and any extra arguments (empty by default).

Defaults to create_key().

EXAMPLES:

```
sage: from sage.structure.test_factory import test_factory
sage: test_factory.create_key_and_extra_args(1, 2, key=5)
((1, 2), {})
sage: GF.create_key_and_extra_args(3, foo='value')
((3, None, None, None, "{'foo': 'value'}", 3, 1, True), {'foo': 'value'})
```

create_object (version, key, **extra_args)

Create the object from the key and extra arguments. This is only called if the object was not found in the cache.

```
sage: from sage.structure.test_factory import test_factory
sage: test_factory.create_object(0, (1,2,3))
Making object (1, 2, 3)
<sage.structure.test_factory.A instance at ...>
sage: test_factory('a')
Making object ('a',)
<sage.structure.test_factory.A instance at ...>
sage: test_factory('a') # NOT called again
<sage.structure.test_factory.A instance at ...>
```

get_object (version, key, extra_args)

Returns the object corresponding to key, creating it with extra_args if necessary (for example, it isn't in the cache or it is unpickling from an older version of Sage).

EXAMPLES:

```
sage: from sage.structure.test_factory import test_factory
sage: a = test_factory.get_object(3.0, 'a', {}); a
Making object a
<sage.structure.test_factory.A instance at ...>
sage: test_factory.get_object(3.0, 'a', {}) is test_factory.get_object(3.0, 'a', {})
True
sage: test_factory.get_object(3.0, 'a', {}) is test_factory.get_object(3.1, 'a', {})
Making object a
False
sage: test_factory.get_object(3.0, 'a', {}) is test_factory.get_object(3.0, 'b', {})
Making object b
False
```

TESTS:

Check that trac ticket #16317 has been fixed, i.e., caching works for unhashable objects:

```
sage: K.<u> = Qq(4)
sage: test_factory.get_object(3.0, (K(1), 'c'), {}) is test_factory.get_object(3.0, (K(1),
Making object (1 + O(2^20), 'c')
True
```

get_version (sage_version)

This is provided to allow more or less granular control over pickle versioning. Objects pickled in the same version of Sage will unpickle to the same rather than simply equal objects. This can provide significant gains as arithmetic must be performed on objects with identical parents. However, if there has been an incompatible change (e.g. in element representation) we want the version number to change so coercion is forced between the two parents.

Defaults to the Sage version that is passed in, but coarser granularity can be provided.

EXAMPLES:

```
sage: from sage.structure.test_factory import test_factory
sage: test_factory.get_version((3,1,0))
(3, 1, 0)
```

other_keys (key, obj)

Sometimes during object creation, certain defaults are chosen which may result in a new (more specific) key. This allows the more specific key to be regarded as equivalent to the original key returned by create_key() for the purpose of lookup in the cache, and is used for pickling.

We use the GF factory to build the finite field with 27 elements and generator k:

reduce data(obj)

The results of this function can be returned from __reduce__(). This is here so the factory internals can change without having to re-write __reduce__() methods that use it.

EXAMPLE:

```
sage: V = FreeModule(ZZ, 5)
sage: factory, data = FreeModule.reduce_data(V)
sage: factory(*data)
Ambient free module of rank 5 over the principal ideal domain Integer Ring
sage: factory(*data) is V
True

sage: from sage.structure.test_factory import test_factory
sage: a = test_factory(1, 2)
Making object (1, 2)
sage: test_factory.reduce_data(a)
(<built-in function generic_factory_unpickle>,
    (<class 'sage.structure.test_factory.UniqueFactoryTester'>,
    (...),
    (1, 2),
    {}))
```

Note that the ellipsis (...) here stands for the Sage version.

```
sage.structure.factory.generic_factory_reduce(self, proto)
```

Used to provide a ___reduce__ method if one does not already exist.

EXAMPLES:

```
sage: V = QQ^6
sage: sage.structure.factory.generic_factory_reduce(V, 1) == V.__reduce_ex__(1)
True
```

```
sage.structure.factory.generic_factory_unpickle(factory, *args)
```

Method used for unpickling the object.

The unpickling mechanism needs a plain Python function to call. It takes a factory as the first argument, passes the rest of the arguments onto the factory's UniqueFactory.get_object() method.

```
sage: V = FreeModule(ZZ, 5)
sage: func, data = FreeModule.reduce_data(V)
sage: func is sage.structure.factory.generic_factory_unpickle
True
sage: sage.structure.factory.generic_factory_unpickle(*data) is V
True
```

TESTS:

The following was enabled in trac ticket #16349. Suppose we have defined (somewhere in the library of an old Sage version) a unique factory; in our example below, it returns polynomial rings. Now suppose that we want to replace the factory by something else, say, a class that provides the unique parent behaviour using UniqueRepresentation. We show here how to make it possible to unpickle a pickle created with the factory, automatically turning it into an instance of the new class.

First, we create the factory. In a doctest, it is needed to explicitly put it into __main__, so that it can be located when pickling. Also, it is needed that we work with a new-style class:

```
sage: from sage.structure.factory import UniqueFactory
sage: import __main
sage: class OldStuff(object):
         def __init__(self, n, **extras):
             self.n = n
. . . . :
         def __repr__(self):
             return "Rotten old thing of level {}".format(self.n)
sage: __main__.OldStuff = OldStuff
sage: class MyFactory(UniqueFactory):
....: def create_object(self, version, key, **extras):
             return OldStuff(key[0])
. . . . :
        def create_key(self, *args):
             return args
sage: F = MyFactory('__main__.F')
sage: __main__.F = F
sage: a = F(3); a
Rotten old thing of level 3
sage: loads(dumps(a)) is a
True
```

Now, we create a pickle (the string returned by dumps (a)):

```
sage: s = dumps(a)
```

We create a new class, derived from UniqueRepresentation, that shall replace the old factory. In particular, the class has to have the same name as the old factory, and has to be put into the same module (here: __main__). We turn it into a sub-class of the old class, but this is just to save the effort of writing a new init method:

```
sage: from sage.structure.unique_representation import UniqueRepresentation
sage: class F(UniqueRepresentation, OldStuff):
....: def __repr__(self):
....: return "Shiny new thing of level {}".format(self.n)
sage: __main__.F = F
```

The old pickle correctly unpickles as an instance of the new class, which is of course different from the instance of the old class, but exhibits unique object behaviour as well:

```
sage: b = loads(s); b
Shiny new thing of level 3
sage: a is b
False
sage: loads(dumps(b)) is b
True
```

sage.structure.factory.lookup_global(name)

Used in unpickling the factory itself.

```
sage: from sage.structure.factory import lookup_global
sage: lookup_global('ZZ')
Integer Ring
sage: lookup_global('sage.rings.all.ZZ')
Integer Ring
```

sage.structure.factory.register_factory_unpickle(name, callable)

Register a callable to handle the unpickling from an old UniqueFactory object.

UniqueFactory pickles use a global name through generic_factory_unpickle(), so the usual register_unpickle_override() cannot be used here.

See Also:

```
generic_factory_unpickle()
```

TESTS:

This is similar to the example given in <code>generic_factory_unpickle()</code>, but here we will use a function to explicitly return a polynomial ring.

First, we create the factory. In a doctest, it is needed to explicitly put it into __main__, so that it can be located when pickling. Also, it is needed that we work with a new-style class:

```
sage: from sage.structure.factory import UniqueFactory, register_factory_unpickle
sage: import __main_
sage: class OldStuff(object):
....: def __init__(self, n, **extras):
. . . . :
             self.n = n
. . . . :
        def __repr__(self):
             return "Rotten old thing of level {}".format(self.n)
       _main__.OldStuff = OldStuff
sage: class MyFactory(UniqueFactory):
....: def create_object(self, version, key, **extras):
             return OldStuff(key[0])
. . . . :
        def create_key(self, *args):
. . . . :
             return args
sage: G = MyFactory('__main__.G')
sage: __main__.G = G
sage: a = G(3); a
Rotten old thing of level 3
sage: loads(dumps(a)) is a
```

Now, we create a pickle (the string returned by dumps (a)):

```
sage: s = dumps(a)
```

We create the function which will handle the unpickling:

```
sage: def foo(n, **kwds):
....: return PolynomialRing(QQ, n, 'x')
sage: register_factory_unpickle('__main__.G', foo)
```

The old pickle correctly unpickles as an explicit polynomial ring:

```
sage: loads(s)
Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
```

CHAPTER

TWELVE

DYNAMIC CLASSES

Why dynamic classes?

The short answer:

- Multiple inheritance is a powerful tool for constructing new classes by combining preexisting building blocks.
- There is a combinatorial explosion in the number of potentially useful classes that can be produced this way.
- The implementation of standard mathematical constructions calls for producing such combinations automatically.
- Dynamic classes, i.e. classes created on the fly by the Python interpreter, are a natural mean to achieve this.

The long answer:

Say we want to construct a new class MyPermutation for permutations in a given set S (in Sage, S will be modelled by a parent, but we won't discuss this point here). First, we have to choose a data structure for the permutations, typically among the following:

- Stored by cycle type
- · Stored by code
- Stored in list notation C arrays of short ints (for small permutations) python lists of ints (for huge permutations) ...
- · Stored by reduced word
- · Stored as a function
- ...

Luckily, the Sage library provides (or will provide) classes implementing each of those data structures. Those classes all share a common interface (or possibly a common abstract base class). So we can just derive our class from the chosen one:

```
class MyPermutation(PermutationCycleType):
    ...
```

Then we may want to further choose a specific memory behavior (unique representation, copy-on-write) which (hopefuly) can again be achieved by inheritance:

```
class MyPermutation (UniqueRepresentation, PermutationCycleType): \dots
```

Finaly, we may want to endow the permutations in S with further operations coming from the (algebraic) structure of S:

- group operations
- or just monoid operations (for a subset of permutations not stable by inverse)
- poset operations (for left/right/Bruhat order)
- word operations (searching for substrings, patterns, ...)

Or any combination thereof. Now, our class typically looks like:

```
 \textbf{class MyPermutation} ( \texttt{UniqueRepresentation}, \ \texttt{PermutationCycleType}, \ \texttt{PosetElement}, \ \texttt{GroupElement}) : \\ \dots
```

Note the combinatorial explosion in the potential number of classes which can be created this way.

In practice, such classes will be used in mathematical constructions like:

```
SymmetricGroup(5).subset(... TODO: find a good example in the context above ...)
```

In such a construction, the structure of the result, and therefore the operations on its elements can only be determined at execution time. Let us take another standard construction:

```
A = cartesian_product(B, C)
```

Depending on the structure of B and C, and possibly on further options passed down by the user, A may be:

- an enumerated set
- a group
- · an algebra
- · a poset
- ...

Or any combination thereof.

Hardcoding classes for all potential combinations would be at best tedious. Furthermore, this would require a cumbersome mechanism to lookup the appropriate class depending on the desired combination.

Instead, one may use the ability of Python to create new classes dynamicaly:

```
type ("class name", tuple of base classes, dictionary of methods)
```

This paradigm is powerful, but there are some technicalities to address. The purpose of this library is to standardize its use within Sage, and in particular to ensure that the constructed classes are reused whenever possible (unique representation), and can be pickled.

Combining dynamic classes and Cython classes

Cython classes cannot inherit from a dynamic class (there might be some partial support for this in the future). On the other hand, such an inheritance can be partially emulated using __getattr__(). See sage.categories.examples.semigroups_cython for an example.

This invokes the nested_pickle on construction.

```
sage: from sage.misc.nested_class import NestedClassMetaclass sage: class A(object): ... __metaclass__
     = NestedClassMetaclass ... class B(object): ... pass ... sage: A.B <class '__main__.A.B'> sage:
     getattr(sys.modules[' main '], 'A.B', 'Not found') <class ' main .A.B'>
class sage.structure.dynamic_class.DynamicMetaclass
     Bases: type
     A metaclass implementing an appropriate reduce-by-construction method
class sage.structure.dynamic class.TestClass
     A class used for checking that introspection works
     bla()
          bla ...
sage.structure.dynamic_class.dynamic_class(name, bases, cls=None, reduction=None,
                                                       doccls=None,
                                                                         prepend_cls_bases=True,
                                                       cache=True)
     INPUT:
         •name - a string
         •bases - a tuple of classes
         •cls - a class or None
         •reduction - a tuple or None
         •doccls - a class or None
         •prepend_cls_bases - a boolean (default: True)
         •cache - a boolean or "ignore reduction" (default: True)
```

Constructs dynamically a new class C with name name, and bases bases. If cls is provided, then its methods will be inserted into C, and its bases will be prepended to bases (unless prepend_cls_bases is False).

The module, documentation and source instrospection is taken from doccls, or cls if doccls is None, or bases [0] if both are None (therefore bases should be non empty if cls 'is 'None).

The constructed class can safely be pickled (assuming the arguments themselves can).

Unless cache is False, the result is cached, ensuring unique representation of dynamic classes.

See sage.structure.dynamic_class for a discussion of the dynamic classes paradigm, and its relevance to Sage.

EXAMPLES:

To setup the stage, we create a class Foo with some methods, cached methods, and lazy attributes, and a class Ror.

```
sage: from sage.misc.lazy_attribute import lazy_attribute
sage: from sage.misc.cachefunc import cached_function
sage: from sage.structure.dynamic_class import dynamic_class
sage: class Foo(object):
          "The Foo class"
          def __init__(self, x):
              self._x = x
          @cached method
. . .
          def f(self):
              return self._x^2
          def g(self):
              return self._x^2
. . .
          @lazy_attribute
. . .
```

```
... def x(self):
... return self._x
...
sage: class Bar:
... def bar(self):
... return self._x^2
```

We now create a class FooBar which is a copy of Foo, except that it also inherits from Bar:

```
sage: FooBar = dynamic_class("FooBar", (Bar,), Foo)
sage: x = FooBar(3)
sage: x.f()
sage: x.f() is x.f()
sage: x.x
sage: x.bar()
sage: FooBar.__name__
'FooBar'
sage: FooBar.__module__
'___main___'
sage: Foo.__bases_
(<type 'object'>,)
sage: FooBar.__bases_
(<type 'object'>, <class __main__.Bar at ...>)
sage: Foo.mro()
[<class '__main__.Foo'>, <type 'object'>]
sage: FooBar.mro()
[<class '__main__.FooBar'>, <type 'object'>, <class __main__.Bar at ...>]
```

Pickling

Dynamic classes are pickled by construction. Namely, upon unpickling, the class will be reconstructed by recalling dynamic_class with the same arguments:

```
sage: type(FooBar).__reduce__(FooBar)
(<function dynamic_class at ...>, ('FooBar', (<class __main__.Bar at ...>,), <class '__main__.Fo</pre>
```

Technically, this is achieved by using a metaclass, since the Python pickling protocol for classes is to pickle by name:

```
sage: type(FooBar)
<class 'sage.structure.dynamic_class.DynamicMetaclass'>
```

The following (meaningless) example illustrates how to customize the result of the reduction:

```
sage: BarFoo = dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (3,)))
sage: type(BarFoo).__reduce__(BarFoo)
(<type 'str'>, (3,))
sage: loads(dumps(BarFoo))
'3'
```

Caching

```
By default, the built class is cached:
sage: dynamic_class("FooBar", (Bar,), Foo) is FooBar
True
sage: dynamic_class("FooBar", (Bar,), Foo, cache=True) is FooBar
True
and the result depends on the reduction:
sage: dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (3,))) is BarFoo
sage: dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (2,))) is BarFoo
False
With cache=False, a new class is created each time:
sage: FooBar1 = dynamic_class("FooBar", (Bar,), Foo, cache=False); FooBar1
<class '__main__.FooBar'>
sage: FooBar2 = dynamic_class("FooBar", (Bar,), Foo, cache=False); FooBar2
<class '__main__.FooBar'>
sage: FooBar1 is FooBar
sage: FooBar2 is FooBar1
False
With cache="ignore_reduction", the class does not depend on the reduction:
sage: BarFoo = dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (3,)), cache="ignore_reduction")
sage: dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (2,)), cache="ignore_reduction") is
True
In particular, the reduction used is that provided upon creating the first class:
sage: dynamic_class("BarFoo", (Foo,), Bar, reduction = (str, (2,)), cache="ignore_reduction")._r
(<type 'str'>, (3,))
 Warning: The behaviour upon creating several dynamic classes from the same data but with different values
 for cache option is currently left unspecified. In other words, for a given application, it is recommended to
 consistently use the same value for that option.
TESTS:
sage: import __main_
```

```
sage: import __main__
sage: __main__.Foo = Foo
sage: __main__.Bar = Bar
sage: x = FooBar(3)
sage: x.__dict__  # Breaks without the __dict__ deletion in dynamic_class_internal
{'_x': 3}
sage: type(FooBar).__reduce__(FooBar)
(<function dynamic_class at ...>, ('FooBar', (<class __main__.Bar at ...>,), <class '__main__.Fo
sage: import cPickle
sage: cPickle.loads(cPickle.dumps(FooBar)) == FooBar
True</pre>
```

We check that instrospection works reasonably:

```
sage: sage.misc.sageinspect.sage_getdoc(FooBar)
    'The Foo class\n'
    Finally, we check that classes derived from UniqueRepresentation are handled gracefuly (despite them also
    using a metaclass):
    sage: FooUnique = dynamic class("Foo", (Bar, UniqueRepresentation))
    sage: loads(dumps(FooUnique)) is FooUnique
    True
sage.structure.dynamic_class.dynamic_class_internal(name, bases, cls=None, re-
                                                            duction=None,
                                                                           doccls=None,
                                                            prepend_cls_bases=True)
    See sage.structure.dynamic_class.dynamic_class? for indirect doctests.
    sage: Foo1 = sage.structure.dynamic_class.dynamic_class_internal("Foo", (object,))
    sage: Foo2 = sage.structure.dynamic_class.dynamic_class_internal("Foo", (object,), doccls = sage
    sage: Foo3 = sage.structure.dynamic_class.dynamic_class_internal("Foo", (object,), cls
                                                                                                  = sage
    sage: all(Foo.__name__ == 'Foo'
                                         for Foo in [Foo1, Foo2, Foo3])
    True
    sage: all(Foo.__bases__ == (object,) for Foo in [Foo1, Foo2, Foo3])
    sage: Foo1.__module__ == object.__module__
    True
    sage: Foo2.__module__ == sage.structure.dynamic_class.TestClass.__module__
    True
    sage: Foo3.__module__ == sage.structure.dynamic_class.TestClass.__module__
    sage: Foo1.__doc__ == object.__doc__
    sage: Foo2.__doc__ == sage.structure.dynamic_class.TestClass.__doc__
    sage: Foo3.__doc__ == sage.structure.dynamic_class.TestClass.__doc__
    We check that instrospection works reasonably:
    sage: import inspect
    sage: inspect.getfile(Foo2)
    '.../sage/structure/dynamic_class.pyc'
    sage: inspect.getfile(Foo3)
    '.../sage/structure/dynamic_class.pyc'
    sage: sage.misc.sageinspect.sage_getsourcelines(Foo2)
    (['class TestClass:...'], ...)
    sage: sage.misc.sageinspect.sage_getsourcelines(Foo3)
    (['class TestClass:...'], ...)
    sage: sage.misc.sageinspect.sage_getsourcelines(Foo2())
    (['class TestClass:...'], ...)
    sage: sage.misc.sageinspect.sage_getsourcelines(Foo3())
    (['class TestClass:...'], ...)
    sage: sage.misc.sageinspect.sage_getsourcelines(Foo3().bla)
           def bla():...'], ...)
```

ELEMENTS, ARRAY AND LISTS WITH CLONE PROTOCOL

Elements, Array and Lists With Clone Protocol

This module defines several classes which are subclasses of Element and which roughly implement the "prototype" design pattern (see [Pro], [GOF]). Those classes are intended to be used to model *mathematical* objects, which are by essence immutable. However, in many occasions, one wants to construct the data-structure encoding of a new mathematical object by small modifications of the data structure encoding some already built object. For the resulting data-structure to correctly encode the mathematical object, some structural invariants must hold. One problem is that, in many cases, during the modification process, there is no possibility but to break the invariants.

For example, in a list modeling a permutation of $\{1, \ldots, n\}$, the integers must be distinct. A very common operation is to take a permutation to make a copy with some small modifications, like exchanging two consecutive values in the list or cycling some values. Though the result is clearly a permutations there's no way to avoid breaking the permutations invariants at some point during the modifications.

The main purpose of this module is to define the class

• ClonableElement as an abstract super class,

and its subclasses:

- ClonableArray for arrays (lists of fixed length) of objects;
- ClonableList for (resizable) lists of objects;
- NormalizedClonableList for lists of objects with a normalization method;
- ClonableIntArray for arrays of int.

See Also:

The following parents from sage.structure.list_clone_demo demonstrate how to use them:

- IncreasingArrays () (see IncreasingArray and the parent class IncreasingArrays)
- IncreasingLists() (see IncreasingList and the parent class IncreasingLists)
- SortedLists () (see SortedList and the parent class SortedLists)
- IncreasingIntArrays() (see IncreasingIntArray and the parent class IncreasingIntArrays)

EXAMPLES:

We now demonstrate how IncreasingArray works, creating an instance el through its parent IncreasingArrays():

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: P = IncreasingArrays()
sage: P([1, 4,8])
[1, 4, 8]
```

If one tries to create this way a list which in not increasing, an error is raised:

```
sage: IncreasingArrays()([5, 4,8])
Traceback (most recent call last):
...
ValueError: array is not increasing
```

Once created modifying el is forbidden:

```
sage: el = P([1, 4 ,8])
sage: el[1] = 3
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

However, you can modify a temporarily mutable clone:

```
sage: with el.clone() as elc:
....: elc[1] = 3
sage: [el, elc]
[[1, 4, 8], [1, 3, 8]]
```

We check that the original and the modified copy now are in a proper immutable state:

```
sage: el.is_immutable(), elc.is_immutable()
(True, True)
sage: elc[1] = 5
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

You can break the property that the list is increasing during the modification:

```
sage: with el.clone() as elc2:
....: elc2[1] = 12
....: print elc2
....: elc2[2] = 25
[1, 12, 8]
sage: elc2
[1, 12, 25]
```

But this property must be restored at the end of the with block; otherwise an error is raised:

```
sage: with elc2.clone() as el3:
....: el3[1] = 100
Traceback (most recent call last):
...
ValueError: array is not increasing
```

Finally, as an alternative to the with syntax one can use:

```
sage: el4 = copy(elc2)
sage: el4[1] = 10
```

```
sage: el4.set_immutable()
sage: el4.check()
```

REFERENCES:

AUTHORS:

• Florent Hivert (2010-03): initial revision

```
class sage.structure.list_clone.ClonableArray
    Bases: sage.structure.list_clone.ClonableElement
```

Array with clone protocol

The class of objects which are Element behave as arrays (i.e. lists of fixed length) and implement the clone protocol. See ClonableElement for details about clone protocol.

INPUT:

- •parent a Parent
- •lst a list
- •check a boolean specifying if the invariant must be checked using method check ().
- •immutable a boolean telling wether the created element is immutable (defaults to True)

See Also:

IncreasingArray for an example of usage.

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: IA = IncreasingArrays()
sage: ia1 = IA([1, 4, 6]); ia1
[1, 4, 6]
sage: with ia1.clone() as ia2:
....: ia2[1] = 5
sage: ia2
[1, 5, 6]
sage: with ia1.clone() as ia2:
....: ia2[1] = 7
Traceback (most recent call last):
....
ValueError: array is not increasing
```

check()

Check that self fulfill the invariants

This is an abstract method. Subclasses are supposed to overload check.

```
sage: from sage.structure.list_clone import ClonableArray
sage: ClonableArray(Parent(), [1,2,3]) # indirect doctest
Traceback (most recent call last):
...
AssertionError: This should never be called, please overload the check method
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: el = IncreasingArrays()([1,2,4]) # indirect doctest
```

```
count (kev)
          Returns number of i's for which s[i] == key
          EXAMPLES:
          sage: from sage.structure.list_clone_demo import IncreasingArrays
          sage: c = IncreasingArrays()([1,2,2,4])
          sage: c.count(1)
          1
          sage: c.count(2)
          sage: c.count(3)
     index (x, start=None, stop=None)
          Returns the smallest k such that s[k] == x and i \le k \le j
          EXAMPLES:
          sage: from sage.structure.list_clone_demo import IncreasingArrays
          sage: c = IncreasingArrays()([1,2,4])
          sage: c.index(1)
          sage: c.index(4)
          sage: c.index(5)
          Traceback (most recent call last):
          ValueError: 5 is not in list
class sage.structure.list_clone.ClonableElement
     Bases: sage.structure.element.Element
     Abstract class for elements with clone protocol
     This class is a subclass of Element and implements the "prototype" design pattern (see [Pro], [GOF]). The
     role of this class is:
         •to manage copy and mutability and hashing of elements
         •to ensure that at the end of a piece of code an object is restored in a meaningful mathematical state.
     A class C inheriting from ClonableElement must implement the following two methods
         •obj.__copy__() - returns a fresh copy of obj
         •obj.check () - returns nothing, raise an exception if obj doesn't satisfies the data structure invariants
     and ensure to call obj._require_mutable() at the beginning of any modifying method.
     Additionally, one can also implement
         •obj. hash () - return the hash value of obj.
```

The following equivalent sequence of instructions can be used if speed is needed, in particular in Cython code:

lot of invariant breaking modifications on new_obj

Then, given an instance obj of C, the following sequences of instructions ensures that the invariants of

new_obj are properly restored at the end:
with obj.clone() as new_obj:

invariants are ensured to be fulfilled

```
new_obj = obj.__copy__()
...
# lot of invariant breaking modifications on new_obj
...
new_obj.set_immutable()
new_obj.check()
# invariants are ensured to be fulfilled
```

Finally, if the class implements the _hash_ method, then ClonableElement ensures that the hash value can only be computed on an immutable object. It furthermore caches it so that it is only computed once.

Warning: for the hash caching mechanism to work correctly, the hash value cannot be 0.

EXAMPLES:

The following code shows a minimal example of usage of ClonableElement. We implement a class or pairs (x, y) such that x < y:

```
sage: from sage.structure.list clone import ClonableElement
sage: class IntPair(ClonableElement):
           def __init__(self, parent, x, y):
                ClonableElement.__init__(self, parent=parent)
. . . . :
                self._x = x
. . . . :
                self._y = y
. . . . :
                self.set immutable()
. . . . :
                self.check()
. . . . :
           def _repr_(self):
. . . . :
                return "(x=%s, y=%s)"%(self._x, self._y)
            def check (self):
. . . . :
                if self._x >= self._y:
                     raise ValueError, "Incorrectly ordered pair"
. . . . :
           def get_x(self): return self._x
. . . . :
            def get_y(self): return self._v
. . . . :
            def set_x(self, v): self._require_mutable(); self._x = v
. . . . :
            def set_y(self, v): self._require_mutable(); self._y = v
. . . . :
```

Note: we don't need to define __copy__ since it is properly inherited from Element.

We now demonstrate the behavior. Let's create an IntPair:

```
sage: myParent = Parent()
sage: el = IntPair(myParent, 1, 3); el
(x=1, y=3)
sage: el.get_x()
1
```

Modifying it is forbidden:

```
sage: el.set_x(4)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

However, you can modify a mutable copy:

```
sage: with el.clone() as el1:
....: el1.set_x(2)
```

```
sage: [el, el1]
[(x=1, y=3), (x=2, y=3)]
We check that the original and the modified copy are in a proper immutable state:
sage: el.is_immutable(), el1.is_immutable()
(True, True)
sage: el1.set_x(4)
Traceback (most recent call last):
ValueError: object is immutable; please change a copy instead.
A modification which doesn't restore the invariant x < y at the end is illegal and raise an exception:
sage: with el.clone() as elc2:
          elc2.set_x(5)
. . . . :
Traceback (most recent call last):
ValueError: Incorrectly ordered pair
clone (check=True)
    Returns a clone that is mutable copy of self.
    INPUT:
       •check – a boolean indicating if self.check () must be called after modifications.
    EXAMPLES:
    sage: from sage.structure.list_clone_demo import IncreasingArrays
    sage: el = IncreasingArrays()([1,2,3])
    sage: with el.clone() as el1:
                el1[2] = 5
    . . . . :
    sage: el1
    [1, 2, 5]
is immutable()
    Returns True if self is immutable (can not be changed) and False if it is not.
    To make self immutable use self.set_immutable().
    EXAMPLES:
    sage: from sage.structure.list_clone_demo import IncreasingArrays
    sage: el = IncreasingArrays()([1,2,3])
    sage: el.is_immutable()
    sage: copy(el).is_immutable()
    False
    sage: with el.clone() as ell:
               print [el.is_immutable(), ell.is_immutable()]
    [True, False]
is_mutable()
    Returns True if self is mutable (can be changed) and False if it is not.
    To make this object immutable use self.set_immutable().
    EXAMPLES:
    sage: from sage.structure.list clone demo import IncreasingArrays
    sage: el = IncreasingArrays()([1,2,3])
```

```
sage: el.is_mutable()
         False
         sage: copy(el).is_mutable()
         sage: with el.clone() as ell:
                   print [el.is_mutable(), el1.is_mutable()]
         [False, True]
     set_immutable()
         Makes self immutable, so it can never again be changed.
         sage: from sage.structure.list_clone_demo import IncreasingArrays
         sage: el = IncreasingArrays()([1,2,3])
         sage: el1 = copy(el); el1.is_mutable()
         sage: el1.set_immutable(); el1.is_mutable()
         False
         sage: el1[2] = 4
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
class sage.structure.list_clone.ClonableIntArray
     Bases: sage.structure.list_clone.ClonableElement
     Array of int with clone protocol
     The class of objects which are Element behave as list of int and implement the clone protocol. See
     ClonableElement for details about clone protocol.
     INPUT:
        •parent - a Parent
        •lst - a list
        •check – a boolean specifying if the invariant must be checked using method check ()
        •immutable – a boolean telling wether the created element is immutable (defaults to True)
     See Also:
     IncreasingIntArray for an example of usage.
     check()
         Check that self fulfill the invariants
         This is an abstract method. Subclasses are supposed to overload check.
         EXAMPLES:
         sage: from sage.structure.list_clone import ClonableArray
         sage: ClonableArray(Parent(), [1,2,3]) # indirect doctest
         Traceback (most recent call last):
         AssertionError: This should never be called, please overload the check method
         sage: from sage.structure.list_clone_demo import IncreasingIntArrays
         sage: el = IncreasingIntArrays()([1,2,4]) # indirect doctest
     index (item)
```

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
         sage: c = IncreasingIntArrays()([1,2,4])
         sage: c.index(1)
         sage: c.index(4)
         sage: c.index(5)
         Traceback (most recent call last):
         ValueError: list.index(x): x not in list
    list()
         Convert self into a Python list.
         EXAMPLE:
         sage: from sage.structure.list_clone_demo import IncreasingIntArrays
         sage: I = IncreasingIntArrays()(range(5))
         sage: I == range(5)
         False
         sage: I.list() == range(5)
         sage: I = IncreasingIntArrays()(range(1000))
         sage: I.list() == range(1000)
         True
class sage.structure.list clone.ClonableList
    Bases: sage.structure.list_clone.ClonableArray
    List with clone protocol
    The class of objects which are Element behave as lists and implement the clone protocol.
    ClonableElement for details about clone protocol.
    See Also:
     IncreasingList for an example of usage.
    append(el)
         Appends el to self
         INPUT: e1 - any object
         EXAMPLES:
         sage: from sage.structure.list_clone_demo import IncreasingLists
         sage: el = IncreasingLists()([1])
         sage: el.append(3)
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
         sage: with el.clone() as elc:
         . . . . :
                 elc.append(4)
         . . . . :
                    elc.append(6)
         sage: elc
         [1, 4, 6]
         sage: with el.clone() as elc:
         ....: elc.append(4)
                   elc.append(2)
         Traceback (most recent call last):
```

```
ValueError: array is not increasing
extend(it)
    Extends self by the content of the iterable it
    INPUT: it – any iterable
    EXAMPLES:
    sage: from sage.structure.list_clone_demo import IncreasingLists
    sage: el = IncreasingLists()([1, 4, 5, 8, 9])
    sage: el.extend((10,11))
    Traceback (most recent call last):
    ValueError: object is immutable; please change a copy instead.
    sage: with el.clone() as elc:
              elc.extend((10,11))
    sage: elc
    [1, 4, 5, 8, 9, 10, 11]
    sage: el2 = IncreasingLists()([15, 16])
    sage: with el.clone() as elc:
               elc.extend(el2)
    . . . . :
    sage: elc
    [1, 4, 5, 8, 9, 15, 16]
    sage: with el.clone() as elc:
    \ldots: elc.extend((6,7))
    Traceback (most recent call last):
    ValueError: array is not increasing
insert (index, el)
    Inserts el in self at position index
    INPUT:
       •el – any object
       •index - any int
    EXAMPLES:
    sage: from sage.structure.list_clone_demo import IncreasingLists
    sage: el = IncreasingLists()([1, 4, 5, 8, 9])
    sage: el.insert(3, 6)
    Traceback (most recent call last):
    ValueError: object is immutable; please change a copy instead.
    sage: with el.clone() as elc:
    . . . . :
              elc.insert(3, 6)
    sage: elc
    [1, 4, 5, 6, 8, 9]
    sage: with el.clone() as elc:
              elc.insert(2, 6)
    Traceback (most recent call last):
    ValueError: array is not increasing
```

```
pop(index=-1)
         Remove self[index] from self and returns it
         INPUT: index - any int, default to -1
         EXAMPLES:
         sage: from sage.structure.list_clone_demo import IncreasingLists
         sage: el = IncreasingLists()([1, 4, 5, 8, 9])
         sage: el.pop()
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
         sage: with el.clone() as elc:
         . . . . :
                 print elc.pop()
         sage: elc
         [1, 4, 5, 8]
         sage: with el.clone() as elc:
         . . . . :
                  print elc.pop(2)
         5
         sage: elc
         [1, 4, 8, 9]
    remove(el)
         Remove the first occurence of el from self
         INPUT: el - any object
         EXAMPLES:
         sage: from sage.structure.list_clone_demo import IncreasingLists
         sage: el = IncreasingLists()([1, 4, 5, 8, 9])
         sage: el.remove(4)
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
         sage: with el.clone() as elc:
               elc.remove(4)
         . . . . :
         sage: elc
         [1, 5, 8, 9]
         sage: with el.clone() as elc:
         ....: elc.remove(10)
         Traceback (most recent call last):
         ValueError: list.remove(x): x not in list
class sage.structure.list_clone.NormalizedClonableList
    Bases: sage.structure.list clone.ClonableList
    List with clone protocol and normal form
    This is a subclass of ClonableList which call a method normalize () at creation and after any modifica-
    tion of its instance.
    See Also:
    SortedList for an example of usage.
    EXAMPLES:
```

We construct a sorted list through its parent:

```
sage: from sage.structure.list_clone_demo import SortedLists
sage: SL = SortedLists()
sage: sl1 = SL([4,2,6,1]); sl1
[1, 2, 4, 6]
Normalization is also performed affer modification:
sage: with sl1.clone() as sl2:
           s12[1] = 12
. . . . :
sage: s12
[1, 4, 6, 12]
normalize()
    Normalize self
    This is an abstract method. Subclasses are supposed to overload normalize().
    self.normalize() is supposed to
       •call self._require_mutable() to check that self is in a proper mutable state
       •modify self to put it in a normal form
    EXAMPLES:
    sage: from sage.structure.list_clone_demo import SortedList, SortedLists
    sage: 1 = SortedList(SortedLists(), [2,3,2], False, False)
    sage: 1
    [2, 2, 3]
    sage: 1.check()
    Traceback (most recent call last):
    ValueError: list is not strictly increasing
```

ELEMENTS, ARRAY AND LISTS WITH CLONE PROTOCOL, DEMONSTRATION CLASSES

Elements, Array and Lists With Clone Protocol, demonstration classes This module demonstrate the usage of the various classes defined in list_clone class sage.structure.list_clone_demo.IncreasingArray Bases: sage.structure.list_clone.ClonableArray A small extension class for testing ClonableArray. MUTABILITY CYTHON IMPLEMENTATION

```
Mutability Cython Implementation
class sage.structure.mutability.Mutability
     Bases: object
     is_immutable()
         Return True if this object is immutable (can not be changed) and False if it is not.
         To make this object immutable use self.set_immutable().
         EXAMPLE:
         sage: v = Sequence([1, 2, 3, 4/5])
         sage: v[0] = 5
         sage: v
         [5, 2, 3, 4/5]
         sage: v.is_immutable()
         sage: v.set_immutable()
         sage: v.is_immutable()
         True
     is_mutable()
     set_immutable()
         Make this object immutable, so it can never again be changed.
         EXAMPLES:
         sage: v = Sequence([1,2,3,4/5])
         sage: v[0] = 5
         sage: v
         [5, 2, 3, 4/5]
         sage: v.set_immutable()
         sage: v[3] = 7
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
\verb|sage.structure.mutability.require_immutable| (f)
     A decorator that requires mutability for a method to be called.
```

EXAMPLES:

sage: class A:

```
def __init__(self, val):
                self._m = val
     . . .
            @require_mutable
     . . .
           def change(self, new_val):
     . . .
                'change self'
     . . .
                self._m = new_val
           @require_immutable
     . . .
           def __hash__(self):
     . . .
                'implement hash'
     . . .
                return hash(self._m)
     . . .
    sage: a = A(5)
    sage: a.change(6)
    sage: hash(a) # indirect doctest
    Traceback (most recent call last):
    ValueError: <type 'instance' > instance is mutable, <function __hash__ at ... > must not be called
    sage: a._is_immutable = True
    sage: hash(a)
    6
    sage: a.change(7)
    Traceback (most recent call last):
    ValueError: <type 'instance' > instance is immutable, <function change at ... > must not be called
    sage: from sage.misc.sageinspect import sage_getdoc
    sage: print sage_getdoc(a.__hash__)
    implement hash
    AUTHORS:
        •Simon King <simon.king@uni-jena.de>
sage.structure.mutability.require_mutable(f)
    A decorator that requires mutability for a method to be called.
    EXAMPLES:
    sage: from sage.structure.mutability import require_mutable, require_immutable
    sage: class A:
            def __init__(self, val):
               self._m = val
     . . .
           @require_mutable
           def change(self, new_val):
     . . .
                'change self'
     . . .

CHAPTER

SIXTEEN

SEQUENCES

A mutable sequence of elements with a common guaranteed category, which can be set immutable.

Sequence derives from list, so has all the functionality of lists and can be used wherever lists are used. When a sequence is created without explicitly given the common universe of the elements, the constructor coerces the first and second element to some *canonical* common parent, if possible, then the second and third, etc. If this is possible, it then coerces everything into the canonical parent at the end. (Note that canonical coercion is very restrictive.) The sequence then has a function universe() which returns either the common canonical parent (if the coercion succeeded), or the category of all objects (Objects()). So if you have a list v and type

```
sage: v = [1, 2/3, 5] sage: w = Sequence(v) sage: w.universe() Rational Field
```

then since w.universe () is \mathbf{Q} , you're guaranteed that all elements of w are rationals:

```
sage: v[0].parent()
Integer Ring
sage: w[0].parent()
Rational Field
```

If you do assignment to w this property of being rationals is guaranteed to be preserved.

```
sage: w[0] = 2 sage: w[0].parent() Rational Field sage: w[0] = 'hi' Traceback (most recent call last): ... TypeError: unable to convert hi to a rational
```

However, if you do w = Sequence(v) and the resulting universe is Objects(), the elements are not guaranteed to have any special parent. This is what should happen, e.g., with finite field elements of different characteristics:

```
sage: v = Sequence([GF(3)(1), GF(7)(1)])
sage: v.universe()
Category of objects
```

You can make a list immutable with v.freeze(). Assignment is never again allowed on an immutable list.

Creation of a sequence involves making a copy of the input list, and substantial coercions. It can be greatly sped up by explicitly specifying the universe of the sequence:

```
sage: v = Sequence(range(10000), universe=ZZ)
TESTS:
sage: v = Sequence([1..5])
sage: loads(dumps(v)) == v
True
```

A mutable list of elements with a common guaranteed universe, which can be set immutable.

A universe is either an object that supports coercion (e.g., a parent), or a category.

INPUT:

- •x a list or tuple instance
- •universe (default: None) the universe of elements; if None determined using canonical coercions and the entire list of elements. If list is empty, is category Objects() of all objects.
- •check (default: True) whether to coerce the elements of x into the universe
- •immutable (default: True) whether or not this sequence is immutable
- •cr (default: False) if True, then print a carriage return after each comma when printing this sequence.
- •cr_str (default: False) if True, then print a carriage return after each comma when calling str() on this sequence.
- •use_sage_types (default: False) if True, coerce the built-in Python numerical types int, long, float, complex to the corresponding Sage types (this makes functions like vector() more flexible)

OUTPUT:

•a sequence

EXAMPLES:

```
sage: v = Sequence(range(10))
sage: v.universe()
<type 'int'>
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We can request that the built-in Python numerical types be coerced to Sage objects:

```
sage: v = Sequence(range(10), use_sage_types=True)
sage: v.universe()
Integer Ring
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

You can also use seq for "Sequence", which is identical to using Sequence:

```
sage: v = seq([1,2,1/1]); v
[1, 2, 1]
sage: v.universe()
Rational Field
sage: v.parent()
Category of sequences in Rational Field
sage: v.parent()([3,4/3])
[3, 4/3]
```

Note that assignment coerces if possible,:

```
sage: v = Sequence(range(10), ZZ)
sage: a = QQ(5)
sage: v[3] = a
sage: parent(v[3])
Integer Ring
sage: parent(a)
```

```
Rational Field
sage: v[3] = 2/3
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

Sequences can be used absolutely anywhere lists or tuples can be used:

```
sage: isinstance(v, list)
True
```

Sequence can be immutable, so entries can't be changed:

```
sage: v = Sequence([1,2,3], immutable=True)
sage: v.is_immutable()
True
sage: v[0] = 5
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

Only immutable sequences are hashable (unlike Python lists), though the hashing is potentially slow, since it first involves conversion of the sequence to a tuple, and returning the hash of that.:

```
sage: v = Sequence(range(10), ZZ, immutable=True)
sage: hash(v)
1591723448  # 32-bit
-4181190870548101704 # 64-bit
```

If you really know what you are doing, you can circumvent the type checking (for an efficiency gain):

```
sage: list.__setitem__(v, int(1), 2/3)  # bad circumvention
sage: v
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
sage: list.__setitem__(v, int(1), int(2))  # not so bad circumvention
```

You can make a sequence with a new universe from an old sequence.:

```
sage: w = Sequence(v, QQ)
sage: w
[0, 2, 2, 3, 4, 5, 6, 7, 8, 9]
sage: w.universe()
Rational Field
sage: w[1] = 2/3
sage: w
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
```

Sequences themselves live in a category, the category of all sequences in the given universe.:

```
sage: w.category()
Category of sequences in Rational Field
```

This is also the parent of any sequence:

```
sage: w.parent()
Category of sequences in Rational Field
```

The default universe for any sequence, if no compatible parent structure can be found, is the universe of all Sage objects.

This example illustrates how every element of a list is taken into account when constructing a sequence.:

```
sage: v = Sequence([1,7,6,GF(5)(3)]); v
[1, 2, 1, 3]
sage: v.universe()
Finite Field of size 5
sage: v.parent()
Category of sequences in Finite Field of size 5
sage: v.parent()([7,8,9])
[2, 3, 4]
```

Bases: sage.structure.sage_object.SageObject, list

A mutable list of elements with a common guaranteed universe, which can be set immutable.

A universe is either an object that supports coercion (e.g., a parent), or a category.

INPUT:

- •x a list or tuple instance
- •universe (default: None) the universe of elements; if None determined using canonical coercions and the entire list of elements. If list is empty, is category Objects() of all objects.
- •check (default: True) whether to coerce the elements of x into the universe
- •immutable (default: True) whether or not this sequence is immutable
- •cr (default: False) if True, then print a carriage return after each comma when printing this sequence.
- •use_sage_types (default: False) if True, coerce the built-in Python numerical types int, long, float, complex to the corresponding Sage types (this makes functions like vector() more flexible)

OUTPUT:

•a sequence

EXAMPLES:

```
sage: v = Sequence(range(10))
sage: v.universe()
<type 'int'>
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We can request that the built-in Python numerical types be coerced to Sage objects:

```
sage: v = Sequence(range(10), use_sage_types=True)
sage: v.universe()
Integer Ring
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

You can also use seq for "Sequence", which is identical to using Sequence:

```
sage: v = seq([1,2,1/1]); v
[1, 2, 1]
sage: v.universe()
Rational Field
sage: v.parent()
Category of sequences in Rational Field
```

```
sage: v.parent()([3,4/3])
[3, 4/3]
Note that assignment coerces if possible,
sage: v = Sequence(range(10), ZZ)
sage: a = QQ(5)
sage: v[3] = a
sage: parent(v[3])
Integer Ring
sage: parent(a)
Rational Field
sage: v[3] = 2/3
Traceback (most recent call last):
TypeError: no conversion of this rational to integer
Sequences can be used absolutely anywhere lists or tuples can be used:
sage: isinstance(v, list)
True
Sequence can be immutable, so entries can't be changed:
sage: v = Sequence([1,2,3], immutable=True)
sage: v.is_immutable()
True
sage: v[0] = 5
Traceback (most recent call last):
ValueError: object is immutable; please change a copy instead.
```

Only immutable sequences are hashable (unlike Python lists), though the hashing is potentially slow, since it first involves conversion of the sequence to a tuple, and returning the hash of that.

```
sage: v = Sequence(range(10), ZZ, immutable=True)
sage: hash(v)
1591723448  # 32-bit
-4181190870548101704  # 64-bit
```

If you really know what you are doing, you can circumvent the type checking (for an efficiency gain):

```
sage: list.__setitem__(v, int(1), 2/3)  # bad circumvention
sage: v
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
sage: list.__setitem__(v, int(1), int(2))  # not so bad circumvention
```

You can make a sequence with a new universe from an old sequence.

```
sage: w = Sequence(v, QQ)
sage: w
[0, 2, 2, 3, 4, 5, 6, 7, 8, 9]
sage: w.universe()
Rational Field
sage: w[1] = 2/3
sage: w
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
```

Sequences themselves live in a category, the category of all sequences in the given universe.

```
sage: w.category()
Category of sequences in Rational Field
```

This is also the parent of any sequence:

```
sage: w.parent()
Category of sequences in Rational Field
```

The default universe for any sequence, if no compatible parent structure can be found, is the universe of all Sage objects.

This example illustrates how every element of a list is taken into account when constructing a sequence.

```
sage: v = Sequence([1,7,6,GF(5)(3)]); v
[1, 2, 1, 3]
sage: v.universe()
Finite Field of size 5
sage: v.parent()
Category of sequences in Finite Field of size 5
sage: v.parent()([7,8,9])
[2, 3, 4]
```

append(x)

EXAMPLES: sage: v = Sequence([1,2,3,4], immutable=True) sage: v.append(34) Traceback (most recent call last): ... ValueError: object is immutable; please change a copy instead. sage: v = Sequence([1/3,2,3,4]) sage: v.append(4) sage: type(v[4]) < type 'sage.rings.rational.Rational'>

category()

EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).category()
Category of sequences in Rational Field
```

extend(iterable)

Extend list by appending elements from the iterable.

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.extend(range(4))
sage: B
[1, 2, 3, 0, 1, 2, 3]
```

insert (index, object)

Insert object before index.

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.insert(10, 5)
sage: B
[1, 2, 3, 5]
```

is immutable()

Return True if this object is immutable (can not be changed) and False if it is not.

To make this object immutable use set_immutable().

EXAMPLE:

```
sage: v = Sequence([1, 2, 3, 4/5])
    sage: v[0] = 5
    sage: v
    [5, 2, 3, 4/5]
    sage: v.is_immutable()
    False
    sage: v.set_immutable()
    sage: v.is_immutable()
    True
is_mutable()
    EXAMPLES:
    sage: a = Sequence ([1, 2/3, -2/5])
    sage: a.is_mutable()
    True
    sage: a[0] = 100
    sage: type(a[0])
    <type 'sage.rings.rational.Rational'>
    sage: a.set_immutable()
    sage: a[0] = 50
    Traceback (most recent call last):
    ValueError: object is immutable; please change a copy instead.
    sage: a.is_mutable()
    False
parent()
    EXAMPLES:
    sage: Sequence([1,2/3,-2/5]).parent()
    Category of sequences in Rational Field
pop(index=-1)
    Remove and return item at index (default last)
    EXAMPLES:
    sage: B = Sequence([1,2,3])
    sage: B.pop(1)
    sage: B
    [1, 3]
remove (value)
    Remove first occurrence of value
    EXAMPLES:
    sage: B = Sequence([1,2,3])
    sage: B.remove(2)
    sage: B
    [1, 3]
reverse()
    Reverse the elements of self, in place.
```

EXAMPLES:

```
sage: B = Sequence([1,2,3])
         sage: B.reverse(); B
         [3, 2, 1]
     set_immutable()
         Make this object immutable, so it can never again be changed.
         EXAMPLES:
         sage: v = Sequence([1,2,3,4/5])
         sage: v[0] = 5
         sage: v
         [5, 2, 3, 4/5]
         sage: v.set_immutable()
         sage: v[3] = 7
         Traceback (most recent call last):
         ValueError: object is immutable; please change a copy instead.
     sort (cmp=None, key=None, reverse=False)
         Sort this list IN PLACE.
         cmp(x, y) \rightarrow -1, 0, 1
         EXAMPLES:
         sage: B = Sequence([3, 2, 1/5])
         sage: B.sort()
         sage: B
         [1/5, 2, 3]
         sage: B.sort(reverse=True); B
         [3, 2, 1/5]
         sage: B.sort(cmp = lambda x,y: cmp(y,x)); B
         [3, 2, 1/5]
         sage: B.sort(cmp = lambda x,y: cmp(y,x), reverse=True); B
         [1/5, 2, 3]
     universe()
         EXAMPLES:
         sage: Sequence ([1,2/3,-2/5]) . universe ()
         Rational Field
         sage: Sequence([1,2/3,'-2/5']).universe()
         Category of objects
sage.structure.sequence.seq(x, universe=None, check=True, immutable=False, cr=False,
                                  cr str=None, use sage types=False)
     A mutable list of elements with a common guaranteed universe, which can be set immutable.
```

A universe is either an object that supports coercion (e.g., a parent), or a category.

INPUT:

- •x a list or tuple instance
- •universe (default: None) the universe of elements; if None determined using canonical coercions and the entire list of elements. If list is empty, is category Objects() of all objects.
- •check (default: True) whether to coerce the elements of x into the universe
- •immutable (default: True) whether or not this sequence is immutable

- •cr (default: False) if True, then print a carriage return after each comma when printing this sequence.
- •cr_str (default: False) if True, then print a carriage return after each comma when calling str() on this sequence.
- •use_sage_types (default: False) if True, coerce the built-in Python numerical types int, long, float, complex to the corresponding Sage types (this makes functions like vector() more flexible)

OUTPUT:

•a sequence

EXAMPLES:

```
sage: v = Sequence(range(10))
sage: v.universe()
<type 'int'>
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We can request that the built-in Python numerical types be coerced to Sage objects:

```
sage: v = Sequence(range(10), use_sage_types=True)
sage: v.universe()
Integer Ring
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

You can also use seq for "Sequence", which is identical to using Sequence:

```
sage: v = seq([1,2,1/1]); v
[1, 2, 1]
sage: v.universe()
Rational Field
sage: v.parent()
Category of sequences in Rational Field
sage: v.parent()([3,4/3])
[3, 4/3]
```

Note that assignment coerces if possible,:

```
sage: v = Sequence(range(10), ZZ)
sage: a = QQ(5)
sage: v[3] = a
sage: parent(v[3])
Integer Ring
sage: parent(a)
Rational Field
sage: v[3] = 2/3
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

Sequences can be used absolutely anywhere lists or tuples can be used:

```
sage: isinstance(v, list)
True
```

Sequence can be immutable, so entries can't be changed:

```
sage: v = Sequence([1,2,3], immutable=True)
sage: v.is_immutable()
True
```

```
sage: v[0] = 5
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

Only immutable sequences are hashable (unlike Python lists), though the hashing is potentially slow, since it first involves conversion of the sequence to a tuple, and returning the hash of that.:

```
sage: v = Sequence(range(10), ZZ, immutable=True)
sage: hash(v)
1591723448  # 32-bit
-4181190870548101704  # 64-bit
```

If you really know what you are doing, you can circumvent the type checking (for an efficiency gain):

```
sage: list.__setitem__(v, int(1), 2/3)  # bad circumvention
sage: v
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
sage: list.__setitem__(v, int(1), int(2))  # not so bad circumvention
```

You can make a sequence with a new universe from an old sequence.:

```
sage: w = Sequence(v, QQ)
sage: w
[0, 2, 2, 3, 4, 5, 6, 7, 8, 9]
sage: w.universe()
Rational Field
sage: w[1] = 2/3
sage: w
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
```

Sequences themselves live in a category, the category of all sequences in the given universe.:

```
sage: w.category()
Category of sequences in Rational Field
```

This is also the parent of any sequence:

```
sage: w.parent()
Category of sequences in Rational Field
```

The default universe for any sequence, if no compatible parent structure can be found, is the universe of all Sage objects.

This example illustrates how every element of a list is taken into account when constructing a sequence.:

```
sage: v = Sequence([1,7,6,GF(5)(3)]); v
[1, 2, 1, 3]
sage: v.universe()
Finite Field of size 5
sage: v.parent()
Category of sequences in Finite Field of size 5
sage: v.parent()([7,8,9])
[2, 3, 4]
```

ELEMENT WRAPPER

Element Wrapper

Wrapping Sage or Python objects as Sage elements.

AUTHORS:

- Nicolas Thiery (2008-2010): Initial version
- Travis Scrimshaw (2013-05-04): Cythonized version

A class for creating dummy parents for testing ElementWrapper

```
class sage.structure.element_wrapper.ElementWrapper
    Bases: sage.structure.element.Element
```

A class for wrapping Sage or Python objects as Sage elements.

EXAMPLES:

```
sage: from sage.structure.element_wrapper import DummyParent
sage: parent = DummyParent("A parent")
sage: o = ElementWrapper(parent, "bla"); o
'bla'
sage: isinstance(o, sage.structure.element.Element)
True
sage: o.parent()
A parent
sage: o.value
'bla'
```

Note that \circ is not an instance of str, but rather contains a str. Therefore, \circ does not inherit the string methods. On the other hand, it is provided with reasonable default implementations for equality testing, hashing, etc.

The typical use case of ElementWrapper is for trivially constructing new element classes from pre-existing Sage or Python classes, with a containment relation. Here we construct the tropical monoid of integers endowed with min as multiplication. There, it is desirable *not* to inherit the factor method from Integer:

```
sage: class MinMonoid(Parent):
....:     def _repr_(self):
....:         return "The min monoid"
....:
sage: M = MinMonoid()
sage: class MinMonoidElement(ElementWrapper):
```

```
...: wrapped_class = Integer
....: def __mul__(self, other):
....: return MinMonoidElement(self.parent(), min(self.value, other.value))
sage: x = MinMonoidElement(M, 5); x
5
sage: x.parent()
The min monoid
sage: x.value
5
sage: y = MinMonoidElement(M, 3)
sage: x * y
```

This example was voluntarily kept to a bare minimum. See the examples in the categories (e.g. Semigroups ().example ()) for several full featured applications.

Warning: Versions before trac ticket #14519 had parent as the second argument and the value as the first.

value

```
class sage.structure.element_wrapper.ElementWrapperTester
    Bases: sage.structure.element_wrapper.ElementWrapper
    Test class for the default __copy () method of subclasses of ElementWrapper.
    TESTS:
    sage: from sage.structure.element_wrapper import ElementWrapperTester
    sage: x = ElementWrapperTester()
    sage: x.append(2); y = copy(x); y.append(42)
    sage: type(y)
    <class 'sage.structure.element_wrapper.ElementWrapperTester'>
    sage: x, y
    ([n=1, value=[2]], [n=2, value=[2, 42]])
    sage: x.append(21); x.append(7)
    sage: x, y
     ([n=3, value=[2, 21, 7]], [n=2, value=[2, 42]])
    sage: x.value, y.value
     ([2, 21, 7], [2, 42])
    sage: x.__dict__, y.__dict__
     ({'n': 3}, {'n': 2})
    append(x)
        TESTS:
         sage: from sage.structure.element_wrapper import ElementWrapperTester
         sage: x = ElementWrapperTester()
         sage: x.append(2); x
         [n=1, value=[2]]
```

INDEXED GENERATORS

Bases: object

Abstract base class for parents whose elements consist of generators indexed by an arbitrary set.

Options controlling the printing of elements:

- •prefix string, prefix used for printing elements of this module (optional, default 'x'). With the default, a monomial indexed by 'a' would be printed as x['a'].
- •latex_prefix string or None, prefix used in the LATEX representation of elements (optional, default None). If this is anything except the empty string, it prints the index as a subscript. If this is None, it uses the setting for prefix, so if prefix is set to "B", then a monomial indexed by 'a' would be printed as B_{a}. If this is the empty string, then don't print monomials as subscripts: the monomial indexed by 'a' would be printed as a, or as [a] if latex_bracket is True.
- •bracket None, bool, string, or list or tuple of strings (optional, default None): if None, use the value of the attribute self._repr_option_bracket, which has default value True. (self._repr_option_bracket is available for backwards compatibility. Users should set bracket instead. If bracket is set to anything except None, it overrides the value of self._repr_option_bracket.) If False, do not include brackets when printing elements: a monomial indexed by 'a' would be printed as B'a', and a monomial indexed by (1,2,3) would be printed as B(1,2,3). If True, use "[" and "]" as brackets. If it is one of "[", "(", or "{", use it and its partner as brackets. If it is any other string, use it as both brackets. If it is a list or tuple of strings, use the first entry as the left bracket and the second entry as the right bracket.
- •latex_bracket bool, string, or list or tuple of strings (optional, default False): if False, do not include brackets in the LaTeX representation of elements. This option is only relevant if latex_prefix is the empty string; otherwise, brackets are not used regardless. If True, use "left[" and "right]" as brackets. If this is one of "[", "(", "\{", "|", or "||", use it and its partner, prepended with "left" and "right", as brackets. If this is any other string, use it as both brackets. If this is a list or tuple of strings, use the first entry as the left bracket and the second entry as the right bracket.
- •scalar_mult string to use for scalar multiplication in the print representation (optional, default "*")
- •latex_scalar_mult string or None (default: None), string to use for scalar multiplication in the latex representation. If None, use the empty string if scalar_mult is set to "*", otherwise use the value of scalar_mult.
- •tensor_symbol string or None (default: None), string to use for tensor product in the print representation. If None, use sage.categories.tensor.symbol.
- •generator_cmp a comparison function (default: cmp), to use for sorting elements in the output of elements

Note: These print options may also be accessed and modified using the print_options () method, after the parent has been defined.

EXAMPLES:

We demonstrate a variety of the input options:

```
sage: from sage.structure.indexed_generators import IndexedGenerators
sage: I = IndexedGenerators(ZZ, prefix='A')
sage: I._repr_generator(2)
'A[2]'
sage: I._latex_generator(2)
'A_{2}'
sage: I = IndexedGenerators(ZZ, bracket='(')
sage: I._repr_generator(2)
'x(2)'
sage: I._latex_generator(2)
'x_{2}'
sage: I = IndexedGenerators(ZZ, prefix="", latex_bracket='(')
sage: I._repr_generator(2)
'[2]'
sage: I._latex_generator(2)
\left( 2 \right)
sage: I = IndexedGenerators(ZZ, bracket=['|', '>'])
sage: I._repr_generator(2)
'x|2>'
indices()
    Return the indices of self.
    EXAMPLES:
    sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
    sage: F.indices()
    {'a', 'b', 'c'}
prefix()
    Return the prefix used when displaying elements of self.
    sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
    sage: F.prefix()
    sage: X = SchubertPolynomialRing(QQ)
    sage: X.prefix()
```

print options(**kwds)

Return the current print options, or set an option.

INPUT: all of the input is optional; if present, it should be in the form of keyword pairs, such as latex_bracket=' ('. The allowable keywords are:

```
•prefix
```

```
•latex_prefix
```

- •bracket
- •latex_bracket
- •scalar_mult
- •latex scalar mult
- •tensor_symbol
- •generator_cmp

See the documentation for CombinatorialFreeModule for descriptions of the effects of setting each of these options.

OUTPUT: if the user provides any input, set the appropriate option(s) and return nothing. Otherwise, return the dictionary of settings for print and LaTeX representations.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [1,2,3], prefix='x')
sage: F.print_options()
{...'prefix': 'x'...}
sage: F.print_options(bracket='(')
sage: F.print_options()
{...'bracket': '('...}

TESTS:
sage: sorted(F.print_options().items())
[('bracket', '('), ('generator_cmp', <built-in function cmp>),
    ('latex_bracket', False), ('latex_prefix', None),
    ('latex_scalar_mult', None), ('prefix', 'x'),
    ('scalar_mult', '*'), ('tensor_symbol', None)]
sage: F.print_options(bracket='[') # reset
```

134

GLOBAL OPTIONS

The GlobalOptions class provides a generic mechanism for setting and accessing **global** options for parents in one or several related classes, typically for customizing the representation of their elements. This class will eventually also support setting options on a parent by parent basis.

See Also:

For better examples of GlobalOptions in action see sage.combinat.partition.Partitions.global_options() and sage.combinat.tableau.Tableaux.global options().

19.1 Construction of options classes

The general setup for creating a set of global options is:

Each option is specified as a dictionary which describes the possible values for the option and its documentation. The possible entries in this dictionary are:

- alias Allows for several option values to do the same thing.
- alt_name An alternative name for this option.
- checker A validation function which returns whether a user supplied value is valid or not. This is typically useful for large lists of legal values such as N.
- default Gives the default value for the option.
- description A one line description of the option.
- link_to Links this option to another one in another set of global options. This is used for example to allow Partitions and Tableaux to share the same convention option.
- setter A function which is called **after** the value of the option is changed.

- values A dictionary assigning each valid value for the option to a short description of what it does.
- case_sensitive (Default: True) True or False depending on whether the values of the option are
 case sensitive.

For each option, either a complete list of possible values, via values, or a validation function, via checker, must be given. The values can be quite arbitrary, including user-defined functions which customize the default behaviour of the classes such as the output of <code>_repr_</code> or <code>latex()</code>. See <code>Dispatchers</code> below, and <code>dispatcher()</code>, for more information.

The documentation for the options is automatically constructed by combining the description of each option with a header and footer which are given by the following optional, but recommended, arguments:

- doc The top half of the documentation which appears before the automatically generated list of options and their possible values.
- end_doc The second half of the documentation which appears after the list of options and their values.

The basic structure for defining a GlobalOptions class is best illustrated by an example:

```
sage: from sage.structure.global_options import GlobalOptions
sage: menu=GlobalOptions('menu', doc='Fancy documentation\n'+'-'*19, end_doc='The END!',
          entree=dict(default='soup',
. . .
                      description='The first course of a meal',
                      values=dict(soup='soup of the day', bread='oven baked'),
                      alias=dict(rye='bread')),
          appetizer=dict(alt_name='entree'),
          main=dict(default='pizza', description='Main meal',
                     values=dict(pizza='thick crust', pasta='penne arrabiata'),
. . .
                     case_sensitive=False),
. . .
          dessert=dict(default='espresso', description='Dessert',
                        values=dict(espresso='life begins again',
                                    cake='waist begins again',
                                    cream='fluffy, white stuff')),
. . .
          tip=dict(default=10, description='Reward for good service',
. . .
          checker=lambda tip: tip in range(0,20))
. . .
      )
. . .
sage: menu
options for menu
```

For more details see GlobalOptions.

19.2 Accessing and setting option values

All options and their values, when they are strings, are forced to be lower case. The values of an options class can be set and accessed by calling the class or by treating the class as an array.

Continuing the example from *Construction of options classes*:

```
sage: menu()
Current options for menu
  - dessert: espresso
  - entree: soup
  - main: pizza
  - tip: 10
sage: menu('dessert')
'espresso'
sage: menu['dessert']
'espresso'
```

Note that, provided there is no ambiguity, options and their values can be abbreviated:

```
sage: menu['d']
'espresso'
sage: menu('m','t',des='esp', ent='sou') # get and set several values at once
['pizza', 10]
sage: menu(t=15); menu['tip']
15
sage: menu(e='s', m='Pi'); menu()
Current options for menu
 - dessert: espresso
 - entree: soup
 - main: pizza
 - tip:
           1.5
sage: menu (m='P')
Traceback (most recent call last):
ValueError: P is not a valid value for main in the options for menu
```

19.3 Setter functions

Each option of a GlobalOptions can be equipped with an optional setter function which is called **after** the value of the option is changed. In the following example, setting the option 'add' changes the state of the class by setting an attribute in this class using a classmethod(). Note that the options object is inserted after the creation of the class in order to access the classmethod() as A.setter:

```
sage: from sage.structure.global_options import GlobalOptions
sage: class A(SageObject):
         state = 0
         @classmethod
         def setter(cls, option, val):
              cls.state += int(val)
sage: A.options=GlobalOptions('A',
                               add=dict(default=1,
. . .
                                        checker=lambda v: int(v)>0,
. . .
                                        description='An option with a setter',
                                        setter=A.setter))
sage: a = A(2); a.state
sage: a.options()
Current options for A
- add: 1
sage: a.options(add=4)
sage: a.state
sage: a.options()
Current options for A
- add: 4
```

Another alternative is to construct the options class inside the __init__ method of the class A.

19.3. Setter functions 137

19.4 Documentation for options

- ''cake'' -- waist begins again
- ''cream'' -- fluffy, white stuff
- ''espresso'' -- life begins again

Current value: espresso

The documentation for a GlobalOptions is automatically generated from the supplied options. For example, the generated documentation for the options menu defined in *Construction of options classes* is the following:

```
Fancy documentation
OPTIONS:
- ''appetizer'' -- alternative name for ''entree''
- ''dessert'' -- (default: ''espresso'')
 Dessert
  - ''cake''
                -- waist begins again
  - ''cream'' -- fluffy, white stuff
  - ''espresso'' -- life begins again
- ''entree'' -- (default: ''soup'')
  The first course of a meal
  - ''bread'' -- oven baked
  - 'rye'' -- alias for bread
  - ''soup'' -- soup of the day
- ''main'' -- (default: ''pizza'')
 Main meal
  - ''pasta'' -- penne arrabiata
  - ''pizza'' -- thick crust
- tip -- (default: 10)
  Reward for good service
The END!
See :class:'~sage.structure.global_options.GlobalOptions' for more features of these options.
In addition, help on each option, and its list of possible values, can be obtained by (trying to) set the option equal to
'?':
sage: menu (des='?')
- ''dessert'' -- (default: ''espresso'')
 Dessert
```

19.5 Dispatchers

The whole idea of a GlobalOptions class is that the options change the default behaviour of the associated classes. This can be done either by simply checking what the current value of the relevant option is. Another possibility is to use the options class as a dispatcher to associated methods. To use the dispatcher feature of a GlobalOptions class it is necessary to implement separate methods for each value of the option where the naming convention for these methods is that they start with a common prefix and finish with the value of the option.

If the value of a dispatchable option is set equal to a (user defined) function then this function is called instead of a class method.

For example, the options MyOptions can be used to dispatch the <u>_repr_</u> method of the associated class MyClass as follows:

```
class MyClass(...):
    global_options=MyOptions
    def _repr_(self):
        return self.global_options.dispatch(self,'_repr_','first_option')
    def _repr_with_bells(self):
        print 'Bell!'
    def _repr_with_whistles(self):
        print 'Whistles!'
```

In this example, first_option is an option of MyOptions which takes values bells, whistles, and so on. Note that it is necessary to make self, which is an instance of MyClass, an argument of the dispatcher because dispatch() is a method of GlobalOptions and not a method of MyClass. Apart from MyOptions, as it is a method of this class, the arguments are the attached class (here MyClass), the prefix of the method of MyClass being dispatched, the option of MyOptions which controls the dispatching. All other arguments are passed through to the corresponding methods of MyClass. In general, a dispatcher is invoked as:

```
self.options.dispatch(self, dispatch_to, option, *args, **kargs)
```

Usually this will result in the method dispatch_to + $'_'$ + MyOptions (options) of self being called with arguments *args and **kargs (if dispatch_to[-1] == $'_'$ then the method dispatch_to + MyOptions (options) is called).

If MyOptions (options) is itself a function then the dispatcher will call this function instead. In this way, it is possible to allow the user to customise the default behaviour of this method. See dispatch() for an example of how this can be achieved.

The dispatching capabilities of GlobalOptions allows options to be applied automatically without needing to parse different values of the option (the cost is that there must be a method for each value). The dispatching capabilities can also be used to make one option control several methods:

```
def __le__(self, other):
    return self.options.dispatch(self, '_le_','cmp', other)
def __ge__(self, other):
    return self.options.dispatch(self, '_ge_','cmp', other)
def _le_option_a(self, other):
    return ...
def _ge_option_a(self, other):
    return ...
def _le_option_b(self, other):
    return ...
def _ge_option_b(self, other):
    return ...
```

See dispatch () for more details.

19.5. Dispatchers 139

19.6 Doc testing

All of the options and their effects should be doc-tested. However, in order not to break other tests, all options should be returned to their default state at the end of each test. To make this easier, every GlobalOptions class has a reset () method for doing exactly this.

19.7 Tests

TESTS:

As options classes to not know how they are created they cannot be pickled:

```
sage: menu=GlobalOptions('menu', doc='Fancy documentation\n'+'-'*19, end_doc='The END!',
          entree=dict(default='soup',
. . .
                      description='The first course of a meal',
                      values=dict(soup='soup of the day', bread='oven baked'),
. . .
                      alias=dict(rye='bread')),
          appetizer=dict(alt_name='entree'),
          main=dict(default='pizza', description='Main meal',
                    values=dict(pizza='thick crust', pasta='penne arrabiata'),
                    case_sensitive=False),
          dessert=dict(default='espresso', description='Dessert',
                       values=dict(espresso='life begins again',
                                   cake='waist begins again',
                                   cream='fluffy, white stuff')),
          tip=dict(default=10, description='Reward for good service',
          checker=lambda tip: tip in range(0,20))
sage: TestSuite(menu).run(skip='_test_pickling')
```

Warning: Default values for GlobalOptions can be automatically overridden by calling the individual instances of the GlobalOptions class inside \$HOME/.sage/init.sage. However, this needs to be disabled by developers when they are writing or checking doc-tests. Another possibly would be to reset () all options before and after all doct-tests which are dependent on particular values of options.

AUTHORS:

• Andrew Mathas (2013): initial version

```
 \textbf{class} \texttt{ sage.structure.global\_options.GlobalOptions} \ (\textit{name}, \textit{doc}=\text{''}, \textit{end\_doc}=\text{''}, **\textit{options}) \\ \textbf{Bases:} \texttt{ sage.structure.sage\_object.SageObject}
```

The GlobalOptions class is a generic class for setting and accessing global options for sage objects. It takes as inputs a name for the collection of options and a dictionary of dictionaries which specifies the individual options. The allowed/expected keys in the dictionary are the following:

INPUTS:

- •name Specifies a name for the options class (required)
 •doc Initial documentation string
- •end_doc Final documentation string
- •<options>=dict(...) Dictionary specifying an option

The options are specified by keyword arguments with their values being a dictionary which describes the option. The allowed/expected keys in the dictionary are:

- •alias Defines alias/synonym for option values
- •alt_name Alternative name for an option
- •checker A function for checking whether a particular value for the option is valid
- •default The default value of the option
- •description Documentation string
- •link to Links to an option for this set of options to an option in another GlobalOptions
- •setter A function (class method) which is called whenever this option changes
- •values A dictionary of the legal values for this option (this automatically defines the corresponding checker). This dictionary gives the possible options, as keys, together with a brief description of them.
- •case_sensitive (Default: True) True or False depending on whether the values of the option are case sensitive.

Options and their values can be abbreviated provided that this abbreviation is a prefix of a unique option.

Calling the options with no arguments results in the list of current options being printed.

EXAMPLES:

```
sage: from sage.structure.global_options import GlobalOptions
entree=dict(default='soup',
. . .
                    description='The first course of a meal',
. . .
                    values=dict(soup='soup of the day', bread='oven baked'),
. . .
                    alias=dict(rye='bread')),
         appetizer=dict(alt_name='entree'),
         main=dict(default='pizza', description='Main meal',
                   values=dict(pizza='thick crust', pasta='penne arrabiata'),
. . .
                   case_sensitive=False),
. . .
         dessert=dict(default='espresso', description='Dessert',
                     values=dict(espresso='life begins again',
                                 cake='waist begins again',
                                 cream='fluffy white stuff')),
         tip=dict(default=10, description='Reward for good service',
. . .
                 checker=lambda tip: tip in range(0,20))
. . .
     )
. . .
sage: menu
options for menu
sage: menu(entree='s')
                             # unambiguous abbreviations are allowed
sage: menu(t=15);
sage: (menu['tip'], menu('t'))
(15, 15)
sage: menu()
Current options for menu
 - dessert: espresso

The documentation for the options class is automatically generated from the information which specifies the
options:
Fancy documentation
OPTIONS:
- dessert: (default: espresso)
 Dessert
                -- waist begins again
  - ''cake''
  - ''cream'' -- fluffy white stuff
  - ''espresso'' -- life begins again
- entree: (default: soup)
 The first course of a meal
  - ''bread'' -- oven baked
  - ''rye'' -- alias for bread
  - ''soup'' -- soup of the day
- main: (default: pizza)
 Main meal
  - ''pasta'' -- penne arrabiata
  - ''pizza'' -- thick crust
- tip: (default: 10)
 Reward for good service
End of Fancy documentation
See :class:'~sage.structure.global_options.GlobalOptions' for more features of these options.
The possible values for an individual option can be obtained by (trying to) set it equal to "?":
sage: menu (des='?')
- ''dessert'' -- (default: ''espresso'')
 Dessert
 - ''cake''
                -- waist begins again
  - ''cream''
               -- fluffy white stuff
  - ''espresso'' -- life begins again
Current value: espresso
default_value(option)
    Return the default value of the option.
    EXAMPLES:
```

dispatch (obj, dispatch_to, option, *args, **kargs)

Todo

title

The dispatchable options are options which dispatch related methods of the corresponding class - or user defined methods which are passed to GlobalOptions. The format for specifying a dispatchable option is to include dispatch_to = <option name> in the specifications for the options and then to add the options to the (element) class. Each option is then assumed to be a method of the element class with a name of the form <option name> + $'_'$ + <current vale for this option'. These options are called by the element class via:

```
return self.options.dispatch(self, dispatch_to, option, *args, **kargs)
```

Note that the argument self is necessary here because the dispatcher is a method of the options class and not of self. The value of the option can also be set to a user-defined function, with arguments self and option; in this case the user's function is called instead.

EXAMPLES:

Here is a contrived example:

reset (option=None)

Reset options to their default value.

INPUT:

•option – (Default: None) The name of an option as a string or None. If option is specified only this option is reset to its default value; otherwise all options are reset.

EXAMPLES:

19.7. Tests 143

```
drink=dict(default='water',values=dict(water='essential for life',wine='essential')
sage: opts(food='salmon'); opts()
Current options for daily meal
    - drink: water
    - food: salmon
sage: opts.reset('drink'); opts()
Current options for daily meal
    - drink: water
    - food: salmon
sage: opts.reset(); opts()
Current options for daily meal
    - drink: water
    - food: bread
```

CARTESIAN PRODUCTS

AUTHORS:

• Nicolas Thiery (2010-03): initial version

A class implementing a raw data structure for cartesian products of sets (and elements thereof). See cartesian_product for how to construct full fledge cartesian products.

```
_cartesian_product_of_elements(elements)
```

Return the cartesian product of the given elements.

 $This implements \verb|Sets.CartesianProducts.ParentMethods._cartesian_product_of_elements(). \\ INPUT:$

•elements – a tuple (or iterable) with one element of each cartesian factor of self

Warning: This is meant as a fast low-level method. In particular, no coercion is attempted. When coercion or sanity checks are desirable, please use instead self(elements) or self._element_constructor(elements).

EXAMPLES:

```
sage: S1 = Sets().example()
sage: S2 = InfiniteEnumeratedSets().example()
sage: C = cartesian_product([S2, S1, S2])
sage: C._cartesian_product_of_elements([S2.an_element(), S1.an_element(), S2.an_element()])
(42, 47, 42)
```

class Element

```
Bases: sage.structure.element_wrapper.ElementWrapper
```

See http://trac.sagemath.org/14519 for details.

```
sage: from sage.structure.element_wrapper import DummyParent
sage: a = ElementWrapper(DummyParent("A parent"), 1)

TESTS:
sage: TestSuite(a).run(skip = "_test_category")

sage: a = ElementWrapper(1, DummyParent("A parent"))
doctest:...: DeprecationWarning: the first argument must be a parent
```

Note: ElementWrapper is not intended to be used directly, hence the failing category test.

```
cartesian_projection(i)
       Return the projection of self on the i-th factor of the cartesian product, as per
       Sets.CartesianProducts.ElementMethods.cartesian_projection().
          •i – the index of a factor of the cartesian product
       EXAMPLES:
       sage: C = Sets().CartesianProducts().example(); C
       The cartesian product of (Set of prime numbers (basic implementation), An example of an
       sage: x = C.an_element(); x
       (47, 42, 1)
       sage: x.cartesian_projection(1)
       42
       sage: x.summand_projection(1)
       doctest:...: DeprecationWarning: summand_projection is deprecated. Please use cartesian_
       See http://trac.sagemath.org/10963 for details.
CartesianProduct.an_element()
    EXAMPLES:
    sage: C = Sets().CartesianProducts().example(); C
    The cartesian product of (Set of prime numbers (basic implementation),
    An example of an infinite enumerated set: the non negative integers,
    An example of a finite enumerated set: \{1,2,3\})
    sage: C.an_element()
    (47, 42, 1)
CartesianProduct.cartesian factors()
    Return the cartesian factors of self.
    See Also:
    Sets.CartesianProducts.ParentMethods.cartesian factors().
    sage: cartesian_product([QQ, ZZ, ZZ]).cartesian_factors()
    (Rational Field, Integer Ring, Integer Ring)
CartesianProduct.cartesian_projection(i)
    Return the natural projection onto the i-th cartesian factor of self as per
    Sets.CartesianProducts.ParentMethods.cartesian_projection().
    INPUT:
      •i - the index of a cartesian factor of self
    EXAMPLES:
    sage: C = Sets().CartesianProducts().example(); C
    The cartesian product of (Set of prime numbers (basic implementation), An example of an infi
    sage: x = C.an_element(); x
    (47, 42, 1)
    sage: pi = C.cartesian_projection(1)
    sage: pi(x)
    42.
```

CartesianProduct.summand_projection(*args, **kwds)

Deprecated: Use cartesian_projection() instead. See trac ticket #10963 for details.

FAMILIES

A Family is an associative container which models a family $(f_i)_{i \in I}$. Then, f[i] returns the element of the family indexed by i. Whenever available, set and combinatorial class operations (counting, iteration, listing) on the family are induced from those of the index set. Families should be created through the Family() function.

AUTHORS:

- Nicolas Thiery (2008-02): initial release
- Florent Hivert (2008-04): various fixes, cleanups and improvements.

TESTS:

Check for workaround trac ticket #12482 (shall be run in a fresh session):

```
sage: P = Partitions(3)
sage: Family(P, lambda x: x).category() # used to return ''enumerated sets''
Category of finite enumerated sets
sage: Family(P, lambda x: x).category()
Category of finite enumerated sets

class sage.sets.family.AbstractFamily
    Bases: sage.structure.parent.Parent
```

The abstract class for family

Any family belongs to a class which inherits from AbstractFamily.

hidden_keys()

Returns the hidden keys of the family, if any.

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: f.hidden_keys()
[]
```

inverse_family()

Returns the inverse family, with keys and values exchanged. This presumes that there are no duplicate values in self.

This default implementation is not lazy and therefore will only work with not too big finite families. It is also cached for the same reason:

```
sage: Family({3: 'a', 4: 'b', 7: 'd'}).inverse_family()
Finite family {'a': 3, 'b': 4, 'd': 7}

sage: Family((3,4,7)).inverse_family()
Finite family {3: 0, 4: 1, 7: 2}
```

```
map(f, name=None)
```

Returns the family $(f(self[i]))_{i \in I}$, where *I* is the index set of self.

Todo

good name?

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: g = f.map(lambda x: x+'1')
sage: list(g)
['a1', 'b1', 'd1']
```

zip (f, other, name=None)

Given two families with same index set I (and same hidden keys if relevant), returns the family $(f(self[i], other[i]))_{i \in I}$

Todo

generalize to any number of families and merge with map?

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: g = Family({3: '1', 4: '2', 7: '3'})
sage: h = f.zip(lambda x,y: x+y, g)
sage: list(h)
['a1', 'b2', 'd3']
```

class sage.sets.family.EnumeratedFamily(enumset)

```
Bases: sage.sets.family.LazyFamily
```

Enumerated Family turns an enumerated set c into a family indexed by the set $\{0,\ldots,|c|-1\}$.

Instances should be created via the Family () factory. See its documentation for examples and tests.

cardinality()

Return the number of elements in self.

EXAMPLES:

```
sage: from sage.sets.family import EnumeratedFamily
sage: f = EnumeratedFamily(Permutations(3))
sage: f.cardinality()
6

sage: from sage.categories.examples.infinite_enumerated_sets import NonNegativeIntegers
sage: f = Family(NonNegativeIntegers())
sage: f.cardinality()
+Infinity
```

keys()

Returns self's keys.

```
sage: from sage.sets.family import EnumeratedFamily
sage: f = EnumeratedFamily(Permutations(3))
sage: f.keys()
```

Standard permutations of 3

```
sage: from sage.categories.examples.infinite_enumerated_sets import NonNegativeIntegers
sage: f = Family(NonNegativeIntegers())
sage: f.keys()
An example of an infinite enumerated set: the non negative integers
```

```
sage.sets.family(indices, function=None, hidden_keys=[], hidden_function=None,
lazy=False, name=None)
```

A Family is an associative container which models a family $(f_i)_{i \in I}$. Then, f[i] returns the element of the family indexed by i. Whenever available, set and combinatorial class operations (counting, iteration, listing) on the family are induced from those of the index set.

There are several available implementations (classes) for different usages; Family serves as a factory, and will create instances of the appropriate classes depending on its arguments.

INPUT:

- •indices the indices for the family
- •function (optional) the function f applied to all visible indices; the default is the identity function
- •hidden_keys (optional) a list of hidden indices that can be accessed through my_family[i]
- •hidden_function (optional) a function for the hidden indices
- •lazy boolean (default: False); whether the family is lazily created or not; if the indices are infinite, then this is automatically made True
- •name (optional) the name of the function; only used when the family is lazily created via a function

EXAMPLES:

In its simplest form, a list $l = [l_0, l_1, \dots, l_\ell]$ or a tuple by itself is considered as the family $(l_i)_{i \in I}$ where I is the set $\{0, \dots, \ell\}$ where ℓ is len (1) - 1. So Family (1) returns the corresponding family:

```
sage: f = Family([1,2,3])
sage: f
Family (1, 2, 3)
sage: f = Family((1,2,3))
sage: f
Family (1, 2, 3)
```

Instead of a list you can as well pass any iterable object:

```
sage: f = Family(2*i+1 \text{ for } i \text{ in } [1,2,3]);

sage: f

Family (3, 5, 7)
```

A family can also be constructed from a dictionary t. The resulting family is very close to t, except that the elements of the family are the values of t. Here, we define the family $(f_i)_{i \in \{3,4,7\}}$ with $f_3 = a$, $f_4 = b$, and $f_7 = d$:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: f
Finite family {3: 'a', 4: 'b', 7: 'd'}
sage: f[7]
'd'
sage: len(f)
3
sage: list(f)
['a', 'b', 'd']
```

```
sage: [ x for x in f ]
['a', 'b', 'd']
sage: f.keys()
[3, 4, 7]
sage: 'b' in f
True
sage: 'e' in f
False
A family can also be constructed by its index set I and a function f, as in (f(i))_{i \in I}:
sage: f = Family([3,4,7], lambda i: 2*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f[7]
14
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
By default, all images are computed right away, and stored in an internal dictionary:
sage: f = Family((3,4,7), lambda i: 2*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
Note that this requires all the elements of the list to be hashable. One can ask instead for the images f(i) to be
computed lazily, when needed:
sage: f = Family([3,4,7], lambda i: 2*i, lazy=True)
sage: f
Lazy family (<lambda>(i))_{i in [3, 4, 7]}
sage: f[7]
14
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
This allows in particular for modeling infinite families:
sage: f = Family(ZZ, lambda i: 2*i, lazy=True)
sage: f
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: f.keys()
Integer Ring
sage: f[1]
sage: f[-5]
-10
sage: i = iter(f)
```

sage: i.next(), i.next(), i.next(), i.next()

(0, 2, -2, 4, -4)

Note that the lazy keyword parameter is only needed to force laziness. Usually it is automatically set to a correct default value (ie: False for finite data structures and True for enumerated sets:

```
sage: f == Family(ZZ, lambda i: 2*i)
True
```

Beware that for those kind of families len(f) is not supposed to work. As a replacement, use the .cardinality() method:

```
sage: f = Family(Permutations(3), attrcall("to_lehmer_code"))
sage: list(f)
[[0, 0, 0], [0, 1, 0], [1, 0, 0], [1, 1, 0], [2, 0, 0], [2, 1, 0]]
sage: f.cardinality()
6
```

Caveat: Only certain families with lazy behavior can be pickled. In particular, only functions that work with Sage's pickle_function and unpickle_function (in sage.misc.fpickle) will correctly unpickle. The following two work:

```
sage: f = Family(Permutations(3), lambda p: p.to_lehmer_code()); f
Lazy family (<lambda>(i))_{i in Standard permutations of 3}
sage: f == loads(dumps(f))
True

sage: f = Family(Permutations(3), attrcall("to_lehmer_code")); f
Lazy family (i.to_lehmer_code())_{i in Standard permutations of 3}
sage: f == loads(dumps(f))
True
```

But this one does not:

```
sage: def plus_n(n): return lambda x: x+n
sage: f = Family([1,2,3], plus_n(3), lazy=True); f
Lazy family (<lambda>(i))_{i in [1, 2, 3]}
sage: f == loads(dumps(f))
Traceback (most recent call last):
...
ValueError: Cannot pickle code objects from closures
```

Finally, it can occasionally be useful to add some hidden elements in a family, which are accessible as f[i], but do not appear in the keys or the container operations:

```
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2])
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
sage: f[7]
14
sage: f[2]
4
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

The following example illustrates when the function is actually called:

```
sage: def compute_value(i):
         print('computing 2*'+str(i))
          return 2*i
sage: f = Family([3,4,7], compute_value, hidden_keys=[2])
computing 2*3
computing 2*4
computing 2*7
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
sage: f[7]
14
sage: f[2]
computing 2*2
sage: f[2]
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
Here is a close variant where the function for the hidden keys is different from that for the other keys:
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2], hidden_function = lambda i: 3*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
sage: f[7]
14
sage: f[2]
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
Family accept finite and infinite EnumeratedSets as input:
sage: f = Family(FiniteEnumeratedSet([1,2,3]))
sage: f
Family (1, 2, 3)
sage: from sage.categories.examples.infinite_enumerated_sets import NonNegativeIntegers
sage: f = Family(NonNegativeIntegers())
Family (An example of an infinite enumerated set: the non negative integers)
sage: f = Family(FiniteEnumeratedSet([3,4,7]), lambda i: 2*i)
sage: f
```

```
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
{3, 4, 7}
sage: f[7]
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
TESTS:
sage: f = Family({1:'a', 2:'b', 3:'c'})
Finite family {1: 'a', 2: 'b', 3: 'c'}
sage: f[2]
sage: loads(dumps(f)) == f
True
sage: f = Family({1:'a', 2:'b', 3:'c'}, lazy=True)
Traceback (most recent call last):
ValueError: lazy keyword only makes sense together with function keyword !
sage: f = Family(range(1,27), lambda i: chr(i+96))
   Finite family {1: 'a', 2: 'b', 3: 'c', 4: 'd', 5: 'e', 6: 'f', 7: 'g', 8: 'h', 9: 'i', 10: '
sage: f[2]
'b'
The factory Family is supposed to be idempotent. We test this feature here:
sage: from sage.sets.family import FiniteFamily, LazyFamily, TrivialFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
sage: g = Family(f)
sage: f == g
True
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2])
sage: g = Family(f)
sage: f == g
True
sage: f = LazyFamily([3,4,7], lambda i: 2*i)
sage: g = Family(f)
sage: f == g
True
sage: f = TrivialFamily([3,4,7])
sage: g = Family(f)
sage: f == q
True
The family should keep the order of the keys:
sage: f = Family(["c", "a", "b"], lambda x: x+x)
sage: list(f)
['cc', 'aa', 'bb']
```

TESTS:

Only the hidden function is applied to the hidden keys:

```
sage: f = lambda x : 2*x
sage: h_f = lambda x:x%2
sage: F = Family([1,2,3,4],function = f, hidden_keys=[5],hidden_function=h_f)
sage: F[5]
```

class sage.sets.family.FiniteFamily(dictionary, keys=None)

```
Bases: sage.sets.family.AbstractFamily
```

A FiniteFamily is an associative container which models a finite family $(f_i)_{i \in I}$. Its elements f_i are therefore its values. Instances should be created via the Family () factory. See its documentation for examples and tests.

EXAMPLES:

We define the family $(f_i)_{i \in \{3,4,7\}}$ with $f_3 = a$, $f_4 = b$, and $f_7 = d$:

```
sage: from sage.sets.family import FiniteFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
```

Individual elements are accessible as in a usual dictionary:

```
sage: f[7]
'd'
```

And the other usual dictionary operations are also available:

```
sage: len(f)
3
sage: f.keys()
[3, 4, 7]
```

However f behaves as a container for the f_i 's:

```
sage: list(f)
['a', 'b', 'd']
sage: [ x for x in f ]
['a', 'b', 'd']
```

The order of the elements can be specified using the keys optional argument:

```
sage: f = FiniteFamily({"a": "aa", "b": "bb", "c" : "cc" }, keys = ["c", "a", "b"])
sage: list(f)
['cc', 'aa', 'bb']
```

cardinality()

Returns the number of elements in self.

EXAMPLES

```
sage: from sage.sets.family import FiniteFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
sage: f.cardinality()
3
```

$has_key(k)$

Returns whether k is a key of self

```
sage: Family({"a":1, "b":2, "c":3}).has_key("a")
         True
         sage: Family({"a":1, "b":2, "c":3}).has_key("d")
         False
     keys()
         Returns the index set of this family
         EXAMPLES:
         sage: f = Family(["c", "a", "b"], lambda x: x+x)
         sage: f.keys()
          ['c', 'a', 'b']
     values()
         Returns the elements of this family
         EXAMPLES:
         sage: f = Family(["c", "a", "b"], lambda x: x+x)
         sage: f.values()
         ['cc', 'aa', 'bb']
class sage.sets.family.FiniteFamilyWithHiddenKeys (dictionary,
                                                                         hidden_keys,
                                                                                         hid-
                                                           den function)
     Bases: sage.sets.family.FiniteFamily
     A close variant of FiniteFamily where the family contains some hidden keys whose corresponding val-
     ues are computed lazily (and remembered). Instances should be created via the Family () factory. See its
     documentation for examples and tests.
     Caveat: Only instances of this class whose functions are compatible with sage.misc.fpickle can be
     pickled.
     hidden_keys()
         Returns self's hidden keys.
         EXAMPLES:
         sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2])
         sage: f.hidden_keys()
         [2]
class sage.sets.family.LazyFamily (set, function, name=None)
     Bases: sage.sets.family.AbstractFamily
     A LazyFamily(I, f) is an associative container which models the (possibly infinite) family (f(i))_{i \in I}.
     Instances should be created via the Family () factory. See its documentation for examples and tests.
     cardinality()
         Return the number of elements in self.
         EXAMPLES:
         sage: from sage.sets.family import LazyFamily
         sage: f = LazyFamily([3,4,7], lambda i: 2*i)
         sage: f.cardinality()
         sage: from sage.categories.examples.infinite_enumerated_sets import NonNegativeIntegers
         sage: 1 = LazyFamily(NonNegativeIntegers(), lambda i: 2*i)
         sage: l.cardinality()
         +Infinity
```

```
TESTS:
         Check that trac ticket #15195 is fixed:
         sage: C = CartesianProduct(PositiveIntegers(), [1,2,3])
         sage: C.cardinality()
         +Infinity
         sage: F = Family(C, lambda x: x)
         sage: F.cardinality()
         +Infinity
     keys()
         Returns self's keys.
         EXAMPLES:
         sage: from sage.sets.family import LazyFamily
         sage: f = LazyFamily([3,4,7], lambda i: 2*i)
         sage: f.keys()
         [3, 4, 7]
class sage.sets.family.TrivialFamily(enumeration)
     Bases: sage.sets.family.AbstractFamily
     TrivialFamily turns a list/tuple c into a family indexed by the set \{0, \ldots, |c| - 1\}.
     Instances should be created via the Family () factory. See its documentation for examples and tests.
     cardinality()
         Return the number of elements in self.
         EXAMPLES:
         sage: from sage.sets.family import TrivialFamily
         sage: f = TrivialFamily([3,4,7])
         sage: f.cardinality()
     keys()
         Returns self's keys.
         EXAMPLES:
         sage: from sage.sets.family import TrivialFamily
         sage: f = TrivialFamily([3,4,7])
         sage: f.keys()
         [0, 1, 2]
```

TWENTYTWO

SETS

AUTHORS:

- William Stein (2005) first version
- William Stein (2006-02-16) large number of documentation and examples; improved code
- Mike Hansen (2007-3-25) added differences and symmetric differences; fixed operators
- Florent Hivert (2010-06-17) Adapted to categories
- Nicolas M. Thiery (2011-03-15) Added subset and superset methods

```
sage.sets.set.Set (X=frozenset([]))
```

Create the underlying set of X.

If X is a list, tuple, Python set, or X.is_finite() is True, this returns a wrapper around Python's enumerated immutable frozenset type with extra functionality. Otherwise it returns a more formal wrapper.

If you need the functionality of mutable sets, use Python's builtin set type.

EXAMPLES:

```
sage: X = Set(GF(9,'a'))
sage: X
{0, 1, 2, a, a + 1, a + 2, 2*a, 2*a + 1, 2*a + 2}
sage: type(X)
<class 'sage.sets.set.Set_object_enumerated_with_category'>
sage: Y = X.union(Set(QQ))
sage: Y
Set-theoretic union of {0, 1, 2, a, a + 1, a + 2, 2*a, 2*a + 1, 2*a + 2} and Set of elements of
sage: type(Y)
<class 'sage.sets.set.Set_object_union_with_category'>
```

Usually sets can be used as dictionary keys.

The original object is often forgotten.

```
sage: v = [1,2,3]
sage: X = Set(v)
sage: X
```

```
{1, 2, 3}
    sage: v.append(5)
    sage: X
     {1, 2, 3}
    sage: 5 in X
    False
    Set also accepts iterators, but be careful to only give finite sets.
    sage: list(Set(iter([1, 2, 3, 4, 5])))
    [1, 2, 3, 4, 5]
    We can also create sets from different types:
    sage: Set([Sequence([3,1], immutable=True), 5, QQ, Partition([3,1,1])])
     {Rational Field, [3, 1, 1], [3, 1], 5}
    However each of the objects must be hashable:
    sage: Set([QQ, [3, 1], 5])
    Traceback (most recent call last):
    TypeError: unhashable type: 'list'
    TESTS:
    sage: Set(Primes())
    Set of all prime numbers: 2, 3, 5, 7, ...
    sage: Set(Subsets([1,2,3])).cardinality()
    sage: Set(iter([1,2,3]))
    {1, 2, 3}
    sage: type(_)
    <class 'sage.sets.set.Set_object_enumerated_with_category'>
    sage: S = Set([])
    sage: TestSuite(S).run()
    Check that trac ticket #16090 is fixed:
    sage: Set()
     { }
class sage.sets.set.Set_object(X)
    Bases: sage.structure.parent.Set_generic
    A set attached to an almost arbitrary object.
    EXAMPLES:
    sage: K = GF(19)
    sage: Set(K)
     \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18\}
    sage: S = Set(K)
    sage: latex(S)
    \left\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18\right\}
    sage: TestSuite(S).run()
    sage: latex(Set(ZZ))
    \Bold{Z}
```

160 Chapter 22. Sets

TESTS:

```
See trac ticket trac ticket #14486:
sage: 0 == Set([1]), Set([1]) == 0
(False, False)
sage: 1 == Set([0]), Set([0]) == 1
(False, False)
an_element()
    Returns the first element of self returned by ___iter___()
    If self is empty, the exception EmptySetError is raised instead.
    This provides a generic implementation of the method _an_element_() for all parents in
    EnumeratedSets.
    EXAMPLES:
    sage: C = FiniteEnumeratedSets().example(); C
    An example of a finite enumerated set: \{1, 2, 3\}
    sage: C.an_element() # indirect doctest
    sage: S = Set([])
    sage: S.an_element()
    Traceback (most recent call last):
    EmptySetError
    TESTS:
    sage: super(Parent, C)._an_element_
    Cached version of <function _an_element_from_iterator at ...>
cardinality()
    Return the cardinality of this set, which is either an integer or Infinity.
    EXAMPLES:
    sage: Set(ZZ).cardinality()
    +Infinity
    sage: Primes().cardinality()
    +Infinity
    sage: Set(GF(5)).cardinality()
    sage: Set(GF(5^2,'a')).cardinality()
    25
difference(X)
    Return the set difference self - X.
    EXAMPLES:
    sage: X = Set(ZZ).difference(Primes())
    sage: 4 in X
    True
    sage: 3 in X
    False
    sage: 4/1 in X
    True
```

sage: X = Set(GF(9,'b')).difference(Set(GF(27,'c')))

```
\{0, 1, 2, b, b + 1, b + 2, 2*b, 2*b + 1, 2*b + 2\}
    sage: X = Set(GF(9,'b')).difference(Set(GF(27,'b')))
    \{0, 1, 2, b, b + 1, b + 2, 2*b, 2*b + 1, 2*b + 2\}
intersection(X)
    Return the intersection of self and X.
    EXAMPLES:
    sage: X = Set(ZZ).intersection(Primes())
    sage: 4 in X
    False
    sage: 3 in X
    True
    sage: 2/1 in X
    True
    sage: X = Set(GF(9,'b')).intersection(Set(GF(27,'c')))
    sage: X
    { }
    sage: X = Set(GF(9, 'b')).intersection(Set(GF(27, 'b')))
    sage: X
    { }
is_empty()
    Return boolean representing emptiness of the set.
    OUTPUT:
    True if the set is empty, false if otherwise.
    EXAMPLES:
    sage: Set([]).is_empty()
    sage: Set([0]).is_empty()
    False
    sage: Set([1..100]).is_empty()
    False
    sage: Set(SymmetricGroup(2).list()).is_empty()
    False
    sage: Set(ZZ).is_empty()
    False
    TESTS:
    sage: Set([]).is_empty()
    True
    sage: Set([1,2,3]).is_empty()
    False
    sage: Set([1..100]).is_empty()
    False
    sage: Set (DihedralGroup(4).list()).is_empty()
    False
    sage: Set(QQ).is_empty()
    False
```

162 Chapter 22. Sets

is finite()

Return True if self is finite.

EXAMPLES:

```
sage: Set(QQ).is_finite()
False
sage: Set(GF(250037)).is_finite()
True
sage: Set(Integers(2^1000000)).is_finite()
True
sage: Set([1,'a',ZZ]).is_finite()
True
```

object()

Return underlying object.

EXAMPLES:

```
sage: X = Set(QQ)
sage: X.object()
Rational Field
sage: X = Primes()
sage: X.object()
Set of all prime numbers: 2, 3, 5, 7, ...
```

subsets (size=None)

Return the Subsets object representing the subsets of a set. If size is specified, return the subsets of that size.

EXAMPLES:

```
sage: X = Set([1,2,3])
sage: list(X.subsets())
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
sage: list(X.subsets(2))
[{1, 2}, {1, 3}, {2, 3}]
```

$symmetric_difference(X)$

Returns the symmetric difference of self and X.

EXAMPLES

```
sage: X = Set([1,2,3]).symmetric_difference(Set([3,4]))
sage: X
{1, 2, 4}
```

$\mathtt{union}\,(X)$

Return the union of self and X.

```
sage: Set(QQ).union(Set(ZZ))
Set-theoretic union of Set of elements of Rational Field and Set of elements of Integer Ring
sage: Set(QQ) + Set(ZZ)
Set-theoretic union of Set of elements of Rational Field and Set of elements of Integer Ring
sage: X = Set(QQ).union(Set(GF(3))); X
Set-theoretic union of Set of elements of Rational Field and {0, 1, 2}
sage: 2/3 in X
True
sage: GF(3)(2) in X
```

```
sage: GF(5)(2) in X
         False
         sage: Set (GF(7)) + Set(GF(3))
         \{0, 1, 2, 3, 4, 5, 6, 1, 2, 0\}
class sage.sets.set.Set_object_difference(X, Y)
     Bases: sage.sets.set.Set_object
     Formal difference of two sets.
     cardinality()
         This tries to return the cardinality of this formal intersection.
           Warning: This is not likely to work in very much generality, and may just hang if either set involved
           is infinite.
         EXAMPLES:
         sage: X = Set(GF(13)).difference(Set(Primes()))
         sage: X.cardinality()
class sage.sets.set.Set_object_enumerated(X)
     Bases: sage.sets.set.Set object
     A finite enumerated set.
     cardinality()
         Return the cardinality of self.
         EXAMPLES:
         sage: Set([1,1]).cardinality()
     difference (other)
         Return the set difference self - other.
         EXAMPLES:
         sage: X = Set([1,2,3,4])
         sage: Y = Set([1,2])
         sage: X.difference(Y)
         {3, 4}
         sage: Z = Set(ZZ)
         sage: W = Set([2.5, 4, 5, 6])
         sage: W.difference(Z)
         {2.500000000000000}
     frozenset()
         Return the Python frozenset object associated to this set, which is an immutable set (hence hashable).
         EXAMPLES:
         sage: X = Set(GF(8,'c'))
         sage: X
         \{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1\}
         sage: s = X.set(); s
         set([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1])
         sage: hash(s)
         Traceback (most recent call last):
```

164 Chapter 22. Sets

```
TypeError: unhashable type: 'set'
    sage: s = X.frozenset(); s
    frozenset([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1)
    sage: hash(s)
    -1390224788
                            # 32-bit
     561411537695332972
                            # 64-bit
    sage: type(s)
    <type 'frozenset'>
intersection (other)
    Return the intersection of self and other.
    EXAMPLES:
    sage: X = Set(GF(8,'c'))
    sage: Y = Set([GF(8,'c').0, 1, 2, 3])
    sage: X.intersection(Y)
    {1, c}
issubset (other)
    Return whether self is a subset of other.
    INPUT:
       •other - a finite Set
    EXAMPLES:
    sage: X = Set([1,3,5])
    sage: Y = Set([0,1,2,3,5,7])
    sage: X.issubset(Y)
    True
    sage: Y.issubset(X)
    False
    sage: X.issubset(X)
    True
    TESTS:
    sage: len([Z for Z in Y.subsets() if Z.issubset(X)])
issuperset (other)
    Return whether self is a superset of other.
    INPUT:
       •other - a finite Set
    EXAMPLES:
    sage: X = Set([1,3,5])
    sage: Y = Set([0,1,2,3,5])
    sage: X.issuperset(Y)
    False
    sage: Y.issuperset(X)
    sage: X.issuperset(X)
    True
```

TESTS:

```
sage: len([Z for Z in Y.subsets() if Z.issuperset(X)])
4
```

list()

Return the elements of self, as a list.

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: X
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1}
sage: X.list()
[0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1]
sage: type(X.list())
<type 'list'>
```

Todo

FIXME: What should be the order of the result? That of self.object()? Or the order given by set(self.object())? Note that __getitem__() is currently implemented in term of this list method, which is really inefficient ...

set()

Return the Python set object associated to this set.

Python has a notion of finite set, and often Sage sets have an associated Python set. This function returns that set.

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: X
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1}
sage: X.set()
set([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1])
sage: type(X.set())
<type 'set'>
sage: type(X)
<class 'sage.sets.set.Set_object_enumerated_with_category'>
```

symmetric_difference (other)

Return the symmetric difference of self and other.

EXAMPLES:

```
sage: X = Set([1,2,3,4])
sage: Y = Set([1,2])
sage: X.symmetric_difference(Y)
{3, 4}
sage: Z = Set(ZZ)
sage: W = Set([2.5, 4, 5, 6])
sage: U = W.symmetric_difference(Z)
sage: 2.5 in U
True
sage: 4 in U
False
sage: V = Z.symmetric_difference(W)
sage: V == U
```

166 Chapter 22. Sets

```
sage: 2.5 in V
         True
         sage: 6 in V
         False
     union (other)
         Return the union of self and other.
         EXAMPLES:
         sage: X = Set(GF(8,'c'))
         sage: Y = Set([GF(8,'c').0, 1, 2, 3])
         \{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1\}
         sage: Y
         {1, c, 3, 2}
         sage: X.union(Y)
         \{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1, 2, 3\}
class sage.sets.set.Set_object_intersection(X, Y)
     Bases: sage.sets.set.Set_object
     Formal intersection of two sets.
     cardinality()
         This tries to return the cardinality of this formal intersection.
           Warning: This is not likely to work in very much generality, and may just hang if either set involved
           is infinite.
         EXAMPLES:
         sage: X = Set(GF(13)).intersection(Set(ZZ))
         sage: X.cardinality()
         13
class sage.sets.set.Set_object_symmetric_difference(X, Y)
     Bases: sage.sets.set.Set_object
     Formal symmetric difference of two sets.
     cardinality()
         Try to return the cardinality of this formal symmetric difference.
         .. WARNING:
         This is not likely to work in very much generality,
         and may just hang if either set involved is infinite.
         EXAMPLES:
```

sage: X = Set(GF(13)).symmetric_difference(Set(range(5)))

A formal union of two sets.

8

sage: X.cardinality()

class sage.sets.set.Set_object_union(X, Y)
 Bases: sage.sets.set_Set_object

cardinality()

Return the cardinality of this set.

EXAMPLES:

```
sage: X = Set(GF(3)).union(Set(GF(2)))
sage: X
{0, 1, 2, 0, 1}
sage: X.cardinality()
5

sage: X = Set(GF(3)).union(Set(ZZ))
sage: X.cardinality()
+Infinity
```

sage.sets.set.is_Set(x)

Returns True if x is a Sage Set_object (not to be confused with a Python set).

EXAMPLES:

```
sage: from sage.sets.set import is_Set
sage: is_Set([1,2,3])
False
sage: is_Set(set([1,2,3]))
False
sage: is_Set(Set([1,2,3]))
True
sage: is_Set(Set(QQ))
True
sage: is_Set(Primes())
```

168 Chapter 22. Sets

DISJOINT-SET DATA STRUCTURE

Disjoint-set data structure

The main entry point is DisjointSet() which chooses the appropriate type to return. For more on the data structure, see DisjointSet().

AUTHORS:

- Sebastien Labbe (2008) Initial version.
- Sebastien Labbe (2009-11-24) Pickling support
- Sebastien Labbe (2010-01) Inclusion into sage (trac ticket #6775).

EXAMPLES:

Disjoint set of integers from 0 to n - 1:

```
sage: s = DisjointSet(6)
sage: s
{{0}, {1}, {2}, {3}, {4}, {5}}
sage: s.union(2, 4)
sage: s.union(1, 3)
sage: s.union(5, 1)
sage: s
{{0}, {1, 3, 5}, {2, 4}}
sage: s.find(3)
1
sage: s.find(5)
1
sage: map(s.find, range(6))
[0, 1, 2, 1, 2, 1]
```

Disjoint set of hashables objects:

```
sage: d = DisjointSet('abcde')
sage: d
{{'a'}, {'b'}, {'c'}, {'d'}, {'e'}}
sage: d.union('a','b')
sage: d.union('b','c')
sage: d.union('c','d')
sage: d
{{'a', 'b', 'c', 'd'}, {'e'}}
sage: d.find('c')
'a'
```

```
sage.sets.disjoint_set.DisjointSet(arg)
```

Constructs a disjoint set where each element of arg is in its own set. If arg is an integer, then the disjoint set returned is made of the integers from 0 to arg -1.

A disjoint-set data structure (sometimes called union-find data structure) is a data structure that keeps track of a partitioning of a set into a number of separate, nonoverlapping sets. It performs two operations:

- •find() Determine which set a particular element is in.
- •union() Combine or merge two sets into a single set.

REFERENCES:

•Wikipedia article Disjoint-set_data_structure

INPUT:

•arg – non negative integer or an iterable of hashable objects.

EXAMPLES:

```
From a non-negative integer:
```

```
sage: DisjointSet(5)
{{0}, {1}, {2}, {3}, {4}}
```

From an iterable:

```
sage: DisjointSet('abcde')
{{'a'}, {'b'}, {'c'}, {'d'}, {'e'}}
sage: DisjointSet(range(6))
{{0}, {1}, {2}, {3}, {4}, {5}}
sage: DisjointSet(['yi', 45,'cheval'])
{{'cheval'}, {'yi'}, {45}}
```

TESTS:

```
sage: DisjointSet(0)
{}
sage: DisjointSet('')
{}
sage: DisjointSet([])
{}
```

The argument must be a non negative integer:

```
sage: DisjointSet(-1)
Traceback (most recent call last):
...
ValueError: arg (=-1) must be a non negative integer

or an iterable:
sage: DisjointSet(4.3)
Traceback (most recent call last):
...
TypeError: 'sage.rings.real_mpfr.RealLiteral' object is not iterable
```

Moreover, the iterable must consist of hashable:

```
sage: DisjointSet([{}, {}])
Traceback (most recent call last):
...
TypeError: unhashable type: 'dict'
```

```
class sage.sets.disjoint_set.DisjointSet_class
    Bases: sage.structure.sage_object.SageObject
    Common class and methods for DisjointSet_of_integers and DisjointSet_of_hashables.
    cardinality()
        Return the number of elements in self, not the number of subsets.
         EXAMPLES:
         sage: d = DisjointSet(5)
         sage: d.cardinality()
        sage: d.union(2, 4)
         sage: d.cardinality()
         sage: d = DisjointSet(range(5))
         sage: d.cardinality()
        sage: d.union(2, 4)
         sage: d.cardinality()
    number of subsets()
        Return the number of subsets in self.
         EXAMPLES:
         sage: d = DisjointSet(5)
         sage: d.number_of_subsets()
        sage: d.union(2, 4)
        sage: d.number_of_subsets()
         sage: d = DisjointSet(range(5))
         sage: d.number_of_subsets()
        sage: d.union(2, 4)
         sage: d.number_of_subsets()
class sage.sets.disjoint_set.DisjointSet_of_hashables
    Bases: sage.sets.disjoint_set.DisjointSet_class
    Disjoint set of hashables.
    EXAMPLES:
    sage: d = DisjointSet('abcde')
    sage: d
    {{'a'}, {'b'}, {'c'}, {'d'}, {'e'}}
    sage: d.union('a', 'c')
    sage: d
     {{'a', 'c'}, {'b'}, {'d'}, {'e'}}
    sage: d.find('a')
    'a'
    TESTS:
    sage: a = DisjointSet('abcdef')
    sage: a == loads(dumps(a))
    True
```

```
sage: a.union('a','c')
sage: a == loads(dumps(a))
True
```

element_to_root_dict()

Return the dictionary where the keys are the elements of self and the values are their representative inside a list.

EXAMPLES:

```
sage: d = DisjointSet(range(5))
sage: d.union(2,3)
sage: d.union(4,1)
sage: e = d.element_to_root_dict(); e
{0: 0, 1: 4, 2: 2, 3: 2, 4: 4}
sage: WordMorphism(e)
WordMorphism: 0->0, 1->4, 2->2, 3->2, 4->4
```

find(e)

Return the representative of the set that e currently belongs to.

INPUT:

•e - element in self

EXAMPLES:

```
sage: e = DisjointSet(range(5))
sage: e.union(4,2)
sage: e
\{\{0\}, \{1\}, \{2, 4\}, \{3\}\}
sage: e.find(2)
sage: e.find(4)
sage: e.union(1,3)
sage: e
{{0}, {1, 3}, {2, 4}}
sage: e.find(1)
sage: e.find(3)
sage: e.union(3,2)
sage: e
{{0}, {1, 2, 3, 4}}
sage: [e.find(i) for i in range(5)]
[0, 1, 1, 1, 1]
sage: e.find(5)
Traceback (most recent call last):
KeyError: 5
```

root_to_elements_dict()

Return the dictionary where the keys are the roots of self and the values are the elements in the same set.

```
sage: d = DisjointSet(range(5))
sage: d.union(2,3)
sage: d.union(4,1)
```

```
sage: e = d.root_to_elements_dict(); e
{0: [0], 2: [2, 3], 4: [1, 4]}
```

to_digraph()

Return the current digraph of self where (a, b) is an oriented edge if b is the parent of a.

EXAMPLES:

```
sage: d = DisjointSet(range(5))
sage: d.union(2,3)
sage: d.union(4,1)
sage: d.union(3,4)
sage: d
{{0}, {1, 2, 3, 4}}
sage: g = d.to_digraph(); g
Looped digraph on 5 vertices
sage: g.edges()
[(0, 0, None), (1, 2, None), (2, 2, None), (3, 2, None), (4, 2, None)]
```

The result depends on the ordering of the union:

```
sage: d = DisjointSet(range(5))
sage: d.union(1,2)
sage: d.union(1,3)
sage: d.union(1,4)
sage: d
{{0}, {1, 2, 3, 4}}
sage: d.to_digraph().edges()
[(0, 0, None), (1, 1, None), (2, 1, None), (3, 1, None), (4, 1, None)]
```

union (e, f)

Combine the set of e and the set of f into one.

All elements in those two sets will share the same representative that can be gotten using find.

INPUT:

- •e element in self
- •f element in self

EXAMPLES:

```
sage: e = DisjointSet('abcde')
sage: e
{{'a'}, {'b'}, {'c'}, {'d'}, {'e'}}
sage: e.union('a','b')
sage: e
{{'a', 'b'}, {'c'}, {'d'}, {'e'}}
sage: e.union('c','e')
sage: e
{{'a', 'b'}, {'c', 'e'}, {'d'}}
sage: e.union('b','e')
sage: e
{{'a', 'b', 'c', 'e'}, {'d'}}
```

class sage.sets.disjoint_set.DisjointSet_of_integers

```
Bases: sage.sets.disjoint_set.DisjointSet_class
```

Disjoint set of integers from 0 to n-1.

```
sage: d = DisjointSet(5)
sage: d
{{0}, {1}, {2}, {3}, {4}}
sage: d.union(2,4)
sage: d.union(0,2)
sage: d
{{0, 2, 4}, {1}, {3}}
sage: d.find(2)
2

TESTS:
sage: a = DisjointSet(5)
sage: a == loads(dumps(a))
True

sage: a.union(3,4)
sage: a == loads(dumps(a))
True
```

element_to_root_dict()

Return the dictionary where the keys are the elements of self and the values are their representative inside a list.

EXAMPLES:

```
sage: d = DisjointSet(5)
sage: d.union(2,3)
sage: d.union(4,1)
sage: e = d.element_to_root_dict(); e
{0: 0, 1: 4, 2: 2, 3: 2, 4: 4}
sage: WordMorphism(e)
WordMorphism: 0->0, 1->4, 2->2, 3->2, 4->4
```

find(i)

Return the representative of the set that i currently belongs to.

INPUT:

 \bullet i - element in self

```
sage: e = DisjointSet(5)
sage: e.union(4,2)
sage: e
{{0}, {1}, {2, 4}, {3}}
sage: e.find(2)
4
sage: e.find(4)
4
sage: e.union(1,3)
sage: e
{{0}, {1, 3}, {2, 4}}
sage: e.find(1)
1
sage: e.find(3)
1
sage: e.union(3,2)
sage: e
{{0}, {1, 2, 3, 4}}
```

```
sage: [e.find(i) for i in range(5)]
[0, 1, 1, 1, 1]
sage: e.find(5)
Traceback (most recent call last):
...
ValueError: i(=5) must be between 0 and 4
```

root_to_elements_dict()

Return the dictionary where the keys are the roots of self and the values are the elements in the same set as the root.

EXAMPLES:

```
sage: d = DisjointSet(5)
sage: d.root_to_elements_dict()
{0: [0], 1: [1], 2: [2], 3: [3], 4: [4]}
sage: d.union(2,3)
sage: d.root_to_elements_dict()
{0: [0], 1: [1], 2: [2, 3], 4: [4]}
sage: d.union(3,0)
sage: d.root_to_elements_dict()
{1: [1], 2: [0, 2, 3], 4: [4]}
sage: d
{{0, 2, 3}, {1}, {4}}
```

to_digraph()

Return the current digraph of self where (a, b) is an oriented edge if b is the parent of a.

EXAMPLES:

```
sage: d = DisjointSet(5)
sage: d.union(2,3)
sage: d.union(4,1)
sage: d.union(3,4)
sage: d
{{0}, {1, 2, 3, 4}}
sage: g = d.to_digraph(); g
Looped digraph on 5 vertices
sage: g.edges()
[(0, 0, None), (1, 2, None), (2, 2, None), (3, 2, None), (4, 2, None)]
```

The result depends on the ordering of the union:

```
sage: d = DisjointSet(5)
sage: d.union(1,2)
sage: d.union(1,3)
sage: d.union(1,4)
sage: d
{{0}, {1, 2, 3, 4}}
sage: d.to_digraph().edges()
[(0, 0, None), (1, 1, None), (2, 1, None), (3, 1, None), (4, 1, None)]
```

union (i, j)

Combine the set of i and the set of j into one.

All elements in those two sets will share the same representative that can be gotten using find.

INPUT:

•i - element in self

```
• j - element in self
         EXAMPLES:
         sage: d = DisjointSet(5)
         sage: d
         \{\{0\}, \{1\}, \{2\}, \{3\}, \{4\}\}
         sage: d.union(0,1)
         sage: d
         {{0, 1}, {2}, {3}, {4}}
         sage: d.union(2,4)
         sage: d
         {{0, 1}, {2, 4}, {3}}
         sage: d.union(1,4)
         sage: d
         {{0, 1, 2, 4}, {3}}
         sage: d.union(1,5)
         Traceback (most recent call last):
         ValueError: j(=5) must be between 0 and 4
sage.sets.disjoint_set.OP_represent (n, merges, perm)
    Demonstration and testing.
    TESTS:
    sage: from sage.groups.perm_gps.partn_ref.automorphism_group_canonical_label import OP_represent
    sage: OP_represent(9, [(0,1),(2,3),(3,4)], [1,2,0,4,3,6,7,5,8])

DISJOINT UNION OF ENUMERATED SETS

AUTHORS:

- Florent Hivert (2009-07/09): initial implementation.
- Florent Hivert (2010-03): classcall related stuff.
- Florent Hivert (2010-12): fixed facade element construction.

 ${\bf class} \; {\tt sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets} \; (\textit{family}, \\$

```
fa-
cade=True,
keep-
key=False,
cat-
e-
gory=None)
```

Bases: sage.structure.unique_representation.UniqueRepresentation,

sage.structure.parent.Parent

A class for disjoint unions of enumerated sets.

INPUT:

- •family a list (or iterable or family) of enumerated sets
- •keepkey a boolean
- •facade a boolean

This models the enumerated set obtained by concatenating together the specified ordered sets. The later are supposed to be pairwise disjoint; otherwise, a multiset is created.

The argument family can be a list, a tuple, a dictionary, or a family. If it is not a family it is first converted into a family (see sage.sets.family.Family()).

Experimental options:

By default, there is no way to tell from which set of the union an element is generated. The option keepkey=True keeps track of those by returning pairs (key, el) where key is the index of the set to which el belongs. When this option is specified, the enumerated sets need not be disjoint anymore.

With the option facade=False the elements are wrapped in an object whose parent is the disjoint union itself. The wrapped object can then be recovered using the 'value' attribute.

The two options can be combined.

The names of those options is imperfect, and subject to change in future versions. Feedback welcome.

EXAMPLES:

The input can be a list or a tuple of FiniteEnumeratedSets:

```
sage: U1 = DisjointUnionEnumeratedSets((
... FiniteEnumeratedSet([1,2,3]),
... FiniteEnumeratedSet([4,5,6])))
sage: U1
Disjoint union of Family ({1, 2, 3}, {4, 5, 6})
sage: U1.list()
[1, 2, 3, 4, 5, 6]
sage: U1.cardinality()
```

The input can also be a dictionary:

However in that case the enumeration order is not specified.

In general the input can be any family:

This allows for infinite unions:

Warning: Beware that some of the operations assume in that case that infinitely many of the enumerated sets are non empty.

Experimental options

We demonstrate the keepkey option:

We now demonstrate the facade option:

Possible extensions: the current enumeration order is not suitable for unions of infinite enumerated sets (except possibly for the last one). One could add options to specify alternative enumeration orders (anti-diagonal, round robin, ...) to handle this case.

Inheriting from DisjointUnionEnumeratedSets

There are two different use cases for inheriting from <code>DisjointUnionEnumeratedSets</code>: writing a parent which happens to be a disjoint union of some known parents, or writing generic disjoint unions for some particular classes of <code>sage.categories.enumerated_sets</code>. <code>EnumeratedSets</code>.

•In the first use case, the input of the __init__ method is most likely different from that of DisjointUnionEnumeratedSets. Then, one simply writes the __init__ method as usual:

In case the __init__() method takes optional arguments, or does some normalization on them, a specific method __classcall_private__ is required (see the documentation of UniqueRepresentation).

```
•In the second use case, the input of the __init__ method is the same as
    that of DisjointUnionEnumeratedSets; one therefore wants to inherit the
    __classcall_private__() method as well, which can be achieved as follows:
    sage: class UnionOfSpecialSets(DisjointUnionEnumeratedSets):
          __classcall_private__ = staticmethod(DisjointUnionEnumeratedSets.__classcall_private_
    sage: psp = UnionOfSpecialSets(Family([1,2], Permutations))
    sage: psp.list()
    [[1], [1, 2], [2, 1]]
TESTS:
sage: TestSuite(U1).run()
sage: TestSuite(U2).run()
sage: TestSuite(U3).run()
sage: TestSuite(U4).run()
doctest:...: UserWarning: Disjoint union of Lazy family (<class 'sage.combinat.permutation.Permu
The default implementation of __contains__ can loop forever. Please overload it.
sage: TestSuite(Ukeep).run()
sage: TestSuite(UNoFacade).run()
The following three lines are required for the pickling tests, because the classes MyUnion and
UnionOfSpecialSets have been defined interactively:
sage: import __main_
sage: __main__.MyUnion = MyUnion
sage: __main__.UnionOfSpecialSets = UnionOfSpecialSets
sage: TestSuite(pp).run()
sage: TestSuite(psp).run()
Element()
    TESTS:
    sage: U = DisjointUnionEnumeratedSets(
                   Family([1,2,3], Partitions), facade=False)
    sage: U.Element
    <type 'sage.structure.element_wrapper.ElementWrapper'>
    sage: U = DisjointUnionEnumeratedSets(
                   Family([1,2,3], Partitions), facade=True)
    sage: U.Element
    Traceback (most recent call last):
    AttributeError: 'DisjointUnionEnumeratedSets_with_category' object has no attribute 'Element
an_element()
    Returns an element of this disjoint union, as per Sets.ParentMethods.an_element().
    EXAMPLES:
    sage: U4 = DisjointUnionEnumeratedSets(
                   Family([3, 5, 7], Permutations))
    sage: U4.an_element()
    [1, 2, 3]
cardinality()
    Returns the cardinality of this disjoint union.
```

EXAMPLES:

For finite disjoint unions, the cardinality is computed by summing the cardinalities of the enumerated sets:

```
sage: U = DisjointUnionEnumeratedSets(Family([0,1,2,3], Permutations))
sage: U.cardinality()
10
```

For infinite disjoint unions, this makes the assumption that the result is infinite:

```
sage: U = DisjointUnionEnumeratedSets(
... Family(NonNegativeIntegers(), Permutations))
sage: U.cardinality()
+Infinity
```

Warning: as pointed out in the main documentation, it is possible to construct examples where this is incorrect:

```
sage: U = DisjointUnionEnumeratedSets(
... Family(NonNegativeIntegers(), lambda x: []))
sage: U.cardinality() # Should be 0!
+Infinity
```

ENUMERATED SET FROM ITERATOR

EXAMPLES:

We build a set from the iterator graphs that returns a canonical representative for each isomorphism class of graphs:

```
sage: from sage.sets.set_from_iterator import EnumeratedSetFromIterator
sage: E = EnumeratedSetFromIterator(
       graphs,
      name = "Graphs",
       category = InfiniteEnumeratedSets(),
        cache = True)
sage: E
Graphs
sage: E.unrank(0)
Graph on 0 vertices
sage: E.unrank(4)
Graph on 3 vertices
sage: E.cardinality()
+Infinity
sage: E.category()
Category of facade infinite enumerated sets
```

The module also provides decorator for functions and methods:

```
sage: from sage.sets.set_from_iterator import set_from_function
sage: @set_from_function
... def f(n): return xsrange(n)
sage: f(3)
{0, 1, 2}
sage: f(5)
{0, 1, 2, 3, 4}
sage: f(100)
{0, 1, 2, 3, 4, ...}
sage: from sage.sets.set_from_iterator import set_from_method
sage: class A:
      @set_from_method
      def f(self,n):
          return xsrange(n)
sage: a = A()
sage: a.f(3)
{0, 1, 2}
sage: f(100)
\{0, 1, 2, 3, 4, \ldots\}
```

```
class sage.sets.set_from_iterator.Decorator
```

Abstract class that manage documentation and sources of the wrapped object.

The method needs to be stored in the attribute self.f

```
class sage.sets.set_from_iterator.DummyExampleForPicklingTest
```

Class example to test pickling with the decorator set_from_method.

Warning: This class is intended to be used in doctest only.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import DummyExampleForPicklingTest
sage: DummyExampleForPicklingTest().f()
{10, 11, 12, 13, 14, ...}
```

f()

Returns the set between self.start and self.stop.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import DummyExampleForPicklingTest
sage: d = DummyExampleForPicklingTest()
sage: d.f()
{10, 11, 12, 13, 14, ...}
sage: d.start = 4
sage: d.stop = 200
sage: d.f()
{4, 5, 6, 7, 8, ...}
```

Bases: sage.structure.parent.Parent

A class for enumerated set built from an iterator.

INPUT:

- •f a function that returns an iterable from which the set is built from
- •args tuple arguments to be sent to the function f
- •kwds dictionnary keywords to be sent to the function f
- •name an optional name for the set
- •category (default: None) an optional category for that enumerated set. If you know that your iterator will stop after a finite number of steps you should set it as FiniteEnumeratedSets, conversly if you know that your iterator will run over and over you should set it as InfiniteEnumeratedSets.
- •cache boolean (default: False) Whether or not use a cache mechanism for the iterator. If True, then the function f is called only once.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import EnumeratedSetFromIterator
sage: E = EnumeratedSetFromIterator(graphs, args = (7,))
sage: E
{Graph on 7 vertices, Graph on 7 vertices, Graph on 7 vertices, Graph on 7 vertices, Graph on 7
```

```
sage: E.category()
Category of facade enumerated sets
The same example with a cache and a custom name:
sage: E = EnumeratedSetFromIterator(
. . .
         graphs,
         args = (8,),
. . .
         category = FiniteEnumeratedSets(),
         name = "Graphs with 8 vertices",
         cache = True)
sage: E
Graphs with 8 vertices
sage: E.unrank(3)
Graph on 8 vertices
sage: E.category()
Category of facade finite enumerated sets
TESTS:
The cache is compatible with multiple call to __iter__:
sage: from itertools import count
sage: E = EnumeratedSetFromIterator(count, args=(0,), category=InfiniteEnumeratedSets(), cache=T
sage: e1 = iter(E)
sage: e2 = iter(E)
sage: e1.next(), e1.next()
(0, 1)
sage: e2.next(), e2.next(), e2.next()
(0, 1, 2)
sage: el.next(), el.next()
(2, 3)
sage: e2.next()
sage: TestSuite(E).run()
sage: E = EnumeratedSetFromIterator(xsrange, args=(10,), category=FiniteEnumeratedSets(), cache=
sage: TestSuite(E).run()
Note: In order to make the TestSuite works, the elements of the set should have parents.
clear cache()
```

```
Clear the cache.

EXAMPLES:

sage: from itertools import count

sage: from sage.sets.set_from_iterator import EnumeratedSetFromIterator

sage: E = EnumeratedSetFromIterator(count, args=(1,), cache=True)

sage: e1 = E._cache

sage: e1

lazy list [1, 2, 3, ...]

sage: E.clear_cache()

sage: E._cache

lazy list [1, 2, 3, ...]

sage: e1 is E._cache

False
```

```
is_parent_of(x)
```

Test whether x is in self.

If the set is infinite, only the answer True should be expected in finite time.

EXAMPLES

```
sage: from sage.sets.set_from_iterator import EnumeratedSetFromIterator
sage: P = Partitions(12,min_part=2,max_part=5)
sage: E = EnumeratedSetFromIterator(P.__iter__)
sage: P([5,5,2]) in E
True
```

unrank(i)

Returns the element at position i.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import EnumeratedSetFromIterator
sage: E = EnumeratedSetFromIterator(graphs, args=(8,), cache=True)
sage: F = EnumeratedSetFromIterator(graphs, args=(8,), cache=False)
sage: E.unrank(2)
Graph on 8 vertices
sage: E.unrank(2) == F.unrank(2)
True
```

 $\begin{tabular}{ll} {\bf class} \ {\tt sage.sets.set_from_iterator.EnumeratedSetFromIterator_function_decorator} \ (\emph{f=None}, \\ \textit{name=None}, \end{tabular}$

**options)

Bases: sage.sets.set_from_iterator.Decorator

Decorator for EnumeratedSetFromIterator.

Name could be string or a function (args, kwds) -> string.

Warning: If you are going to use this with the decorator cached_function, you must place the cached_function first. See the example below.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import set_from_function
sage: @set_from_function
... def f(n):
...     for i in xrange(n):
...         yield i**2 + i + 1
sage: f(3)
{1, 3, 7}
sage: f(100)
{1, 3, 7, 13, 21, ...}
```

To avoid ambiguity, it is always better to use it with a call which provides optional global initialization for the call to EnumeratedSetFromIterator:

```
sage: @set_from_function(category=InfiniteEnumeratedSets())
... def Fibonacci():
...         a = 1;         b = 2
...         while True:
...         yield a
...         a,b = b,a+b
sage: F = Fibonacci()
```

```
sage: F
    {1, 2, 3, 5, 8, ...}
    sage: F.cardinality()
    +Infinity
    A simple example with many options:
    sage: @set_from_function(
               name = "From %(m)d to %(n)d",
                category = FiniteEnumeratedSets())
     ... def f(m,n): return xsrange(m,n+1)
    sage: E = f(3,10); E
    From 3 to 10
    sage: E.list()
    [3, 4, 5, 6, 7, 8, 9, 10]
    sage: E = f(1,100); E
    From 1 to 100
    sage: E.cardinality()
    sage: f(n=100, m=1) == E
    True
    An example which mixes together set_from_function and cached_method:
    sage: @cached_function
     ... @set_from_function(
           name = "Graphs on %(n)d vertices",
           category = FiniteEnumeratedSets(),
           cache = True)
     ... def Graphs (n): return graphs (n)
    sage: Graphs(10)
    Graphs on 10 vertices
    sage: Graphs(10).unrank(0)
    Graph on 10 vertices
    sage: Graphs(10) is Graphs(10)
    True
    The cached_function must go first:
    sage: @set_from_function(
     . . .
          name = "Graphs on %(n)d vertices",
     . . .
           category = FiniteEnumeratedSets(),
           cache = True)
     ... @cached_function
     ... def Graphs (n): return graphs (n)
    sage: Graphs(10)
    Graphs on 10 vertices
    sage: Graphs(10).unrank(0)
    Graph on 10 vertices
    sage: Graphs(10) is Graphs(10)
    False
class sage.sets.set_from_iterator.EnumeratedSetFromIterator_method_caller(inst,
                                                                                   f,
                                                                                   name=None,
                                                                                   **op-
                                                                                   tions)
    Bases: sage.sets.set_from_iterator.Decorator
```

Caller for decorated method in class.

INPUT:

- •inst an instance of a class
- •f a method of a class of inst (and not of the instance itself)
- •name optional either a string (which may contains substitution rules from argument or a function args,kwds -> string.
- •options any option accepted by EnumeratedSetFromIterator

Bases: object

Decorator for enumerated set built from a method.

INPUT:

- •f Optional function from which are built the enumerated sets at each call
- •name Optional string (which may contains substitution rules from argument) or a function (args, kwds) -> string.
- •any option accepted by EnumeratedSetFromIterator.

EXAMPLES:

```
sage: from sage.sets.set_from_iterator import set_from_method
sage: class A():
...    def n(self): return 12
...    @set_from_method
...    def f(self): return xsrange(self.n())
sage: a = A()
sage: print a.f.__class__
sage.sets.set_from_iterator.EnumeratedSetFromIterator_method_caller
sage: a.f()
{0, 1, 2, 3, 4, ...}
sage: A.f(a)
{0, 1, 2, 3, 4, ...}
```

A more complicated example with a parametrized name:

And a last example with a name parametrized by a function:

```
sage: class D():
      def __init__(self, name): self.name = str(name)
       def __str__(self): return self.name
       @set_from_method(
           name = lambda self,n: str(self)*n,
. . .
           category = FiniteEnumeratedSets())
      def subset(self, n):
           return xsrange(n)
sage: d = D('a')
sage: E = d.subset(3); E
sage: E.list()
[0, 1, 2]
sage: F = d.subset(n=10); F
aaaaaaaaa
sage: F.list()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

Todo

It is not yet possible to use set_from_method in conjunction with cached_method.

```
sage.sets.set_from_iterator.set_from_function
    alias of EnumeratedSetFromIterator_function_decorator
sage.sets.set_from_iterator.set_from_method
    alias of EnumeratedSetFromIterator_method_decorator
```

FINITE ENUMERATED SETS

A class for finite enumerated set.

Returns the finite enumerated set with elements in elements where element is any (finite) iterable object.

The main purpose is to provide a variant of list or tuple, which is a parent with an interface consistent with EnumeratedSets and has unique representation. The list of the elements is expanded in memory.

EXAMPLES:

```
sage: S = FiniteEnumeratedSet([1, 2, 3])
sage: S
{1, 2, 3}
sage: S.list()
[1, 2, 3]
sage: S.cardinality()
3
sage: S.random_element()
1
sage: S.first()
1
sage: S.category()
Category of facade finite enumerated sets
sage: TestSuite(S).run()
```

Note that being and enumerated set, the result depends on the order:

```
sage: S1 = FiniteEnumeratedSet((1, 2, 3))
sage: S1
{1, 2, 3}
sage: S1.list()
[1, 2, 3]
sage: S1 == S
True
sage: S2 = FiniteEnumeratedSet((2, 1, 3))
sage: S2 == S
False
```

As an abuse, repeated entries in elements are allowed to model multisets:

```
sage: S1 = FiniteEnumeratedSet((1, 2, 1, 2, 2, 3))
sage: S1
{1, 2, 1, 2, 2, 3}
```

```
Finaly the elements are not aware of their parent:
sage: S.first().parent()
Integer Ring
an_element()
    TESTS:
    sage: S = FiniteEnumeratedSet([1,2,3])
    sage: S.an_element()
    1
cardinality()
    TESTS:
    sage: S = FiniteEnumeratedSet([1,2,3])
    sage: S.cardinality()
first()
    Return the first element of the enumeration or raise an EmptySetError if the set is empty.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet('abc')
    sage: S.first()
    'a'
index(x)
    Returns the index of x in this finite enumerated set.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet(['a','b','c'])
    sage: S.index('b')
    1
is_parent_of(x)
    TESTS:
    sage: S = FiniteEnumeratedSet([1,2,3])
    sage: 1 in S
    True
    sage: 2 in S
    True
    sage: 4 in S
    False
    sage: ZZ in S
    False
    sage: S.is_parent_of(2)
    True
    sage: S.is_parent_of(4)
    False
last()
    Returns the last element of the iteration or raise an EmptySetError if the set is empty.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet([0,'a',1.23, 'd'])
    sage: S.last()
    ' d'
```

```
list()
    TESTS:
    sage: S = FiniteEnumeratedSet([1,2,3])
    sage: S.list()
    [1, 2, 3]
random_element()
    Return a random element.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet('abc')
    sage: S.random_element() # random
    'b'
rank(x)
    Returns the index of x in this finite enumerated set.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet(['a','b','c'])
    sage: S.index('b')
unrank(i)
    Return the element at position i.
    EXAMPLES:
    sage: S = FiniteEnumeratedSet([1,'a',-51])
    sage: S[0], S[1], S[2]
    (1, 'a', -51)
    sage: S[3]
    Traceback (most recent call last):
    IndexError: list index out of range
    sage: S[-1], S[-2], S[-3]
    (-51, 'a', 1)
    sage: S[-4]
    Traceback (most recent call last):
    IndexError: list index out of range
```

RECURSIVELY ENUMERATED SET

Recursively enumerated set

A set S is called recursively enumerable if there is an algorithm that enumerates the members of S. We consider here the recursively enumerated sets that are described by some seeds and a successor function successors. The successor function may have some structure (symmetric, graded, forest) or not. The elements of a set having a symmetric, graded or forest structure can be enumerated uniquely without keeping all of them in memory. Many kinds of iterators are provided in this module: depth first search, breadth first search or elements of given depth.

See Wikipedia article Recursively_enumerable_set.

See documentation of ${\tt RecursivelyEnumeratedSet}$ () below for the description of the inputs.

AUTHORS:

• Sebastien Labbe, April 2014, at Sage Days 57, Cernay-la-ville

EXAMPLES:

27.1 Forest structure

The set of words over the alphabet $\{a,b\}$ can be generated from the empty word by appending letter a or b as a successor function. This set has a forest structure:

```
sage: seeds = ['']
sage: succ = lambda w: [w+'a', w+'b']
sage: C = RecursivelyEnumeratedSet(seeds, succ, structure='forest')
sage: C
An enumerated set with a forest structure
```

Depth first search iterator:

```
sage: it = C.depth_first_search_iterator()
sage: [next(it) for _ in range(6)]
['', 'a', 'aa', 'aaaa', 'aaaaa']
```

Breadth first search iterator:

```
sage: it = C.breadth_first_search_iterator()
sage: [next(it) for _ in range(6)]
['', 'a', 'b', 'aa', 'ab', 'ba']
```

27.2 Symmetric structure

The origin (0, 0) as seed and the upper, lower, left and right lattice point as successor function. This function is symmetric:

```
sage: succ = lambda a: [(a[0]-1,a[1]), (a[0],a[1]-1), (a[0]+1,a[1]), (a[0],a[1]+1)]
sage: seeds = [(0,0)]
sage: C = RecursivelyEnumeratedSet(seeds, succ, structure='symmetric', enumeration='depth')
sage: C
A recursively enumerated set with a symmetric structure (depth first search)
```

In this case, depth first search is the default enumeration for iteration:

```
sage: it_depth = iter(C)
sage: [next(it_depth) for _ in range(10)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (0, 5), (0, 6), (0, 7), (0, 8), (0, 9)]
```

Breadth first search:

```
sage: it_breadth = C.breadth_first_search_iterator()
sage: [next(it_breadth) for _ in range(10)]
[(0, 0), (0, 1), (0, -1), (1, 0), (-1, 0), (-1, 1), (-2, 0), (0, 2), (2, 0), (-1, -1)]
```

Levels (elements of given depth):

```
sage: sorted(C.graded_component(0))
[(0, 0)]
sage: sorted(C.graded_component(1))
[(-1, 0), (0, -1), (0, 1), (1, 0)]
sage: sorted(C.graded_component(2))
[(-2, 0), (-1, -1), (-1, 1), (0, -2), (0, 2), (1, -1), (1, 1), (2, 0)]
```

27.3 Graded structure

Identity permutation as seed and permutohedron_succ as successor function:

```
sage: succ = attrcall("permutohedron_succ")
sage: seed = [Permutation([1..5])]
sage: R = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: R
A recursively enumerated set with a graded structure (breadth first search)
```

Depth first search iterator:

Breadth first search iterator:

```
sage: it_breadth = R.breadth_first_search_iterator()
sage: [next(it_breadth) for _ in range(5)]
[[1, 2, 3, 4, 5],
        [1, 3, 2, 4, 5],
        [1, 2, 4, 3, 5],
        [2, 1, 3, 4, 5],
        [1, 2, 3, 5, 4]]
```

Elements of given depth iterator:

```
sage: list(R.elements_of_depth_iterator(9))
[[5, 4, 2, 3, 1], [4, 5, 3, 2, 1], [5, 3, 4, 2, 1], [5, 4, 3, 1, 2]]
sage: list(R.elements_of_depth_iterator(10))
[[5, 4, 3, 2, 1]]
```

Graded components (set of elements of the same depth):

```
sage: sorted(R.graded_component(0))
[[1, 2, 3, 4, 5]]
sage: sorted(R.graded_component(1))
[[1, 2, 3, 5, 4], [1, 2, 4, 3, 5], [1, 3, 2, 4, 5], [2, 1, 3, 4, 5]]
sage: sorted(R.graded_component(9))
[[4, 5, 3, 2, 1], [5, 3, 4, 2, 1], [5, 4, 2, 3, 1], [5, 4, 3, 1, 2]]
sage: sorted(R.graded_component(10))
[[5, 4, 3, 2, 1]]
```

27.4 No hypothesis on the structure

By "no hypothesis" is meant neither a forest, neither symmetric neither graded, it may have other structure like not containing oriented cycle but this does not help for enumeration.

In this example, the seed is 0 and the successor function is either +2 or +3. This is the set of non negative linear combinaisons of 2 and 3:

```
sage: succ = lambda a:[a+2,a+3]
sage: C = RecursivelyEnumeratedSet([0], succ)
sage: C
A recursively enumerated set (breadth first search)
```

Breadth first search:

```
sage: it = C.breadth_first_search_iterator()
sage: [next(it) for _ in range(10)]
[0, 2, 3, 4, 5, 6, 8, 9, 7, 10]
```

Depth first search:

```
sage: it = C.depth_first_search_iterator()
sage: [next(it) for _ in range(10)]
[0, 3, 6, 9, 12, 15, 18, 21, 24, 27]
```

Return a recursively enumerated set.

A set S is called recursively enumerable if there is an algorithm that enumerates the members of S. We consider here the recursively enumerated set that are described by some seeds and a successor function successors.

Let U be a set and $\verb+successors+: U \to 2^U$ be a successor function associating to each element of U a subset of U. Let $\verb+seeds+$ be a subset of U. Let $S \subseteq U$ be the set of elements of U that can be reached from a seed by applying recursively the $\verb+successors+$ function. This class provides different kinds of iterators (breadth first, depth first, elements of given depth, etc.) for the elements of S.

See Wikipedia article Recursively_enumerable_set.

INPUT:

- •seeds list (or iterable) of hashable objects
- •successors function (or callable) returning a list (or iterable) of hashable objects
- •structure string (optional, default: None), structure of the set, possible values are:
 - -None nothing is known about the structure of the set.
 - -' forest' if the successors function generates a *forest*, that is, each element can be reached uniquely from a seed.
 - -' graded' if the successors function is *graded*, that is, all paths from a seed to a given element have equal length.
 - -' symmetric' if the relation is symmetric, that is, y in successors (x) if and only if x in successors (y)
- •enumeration 'depth', 'breadth', 'naive' or None (optional, default: None). The default enumeration for the __iter__ function.
- •max_depth integer (optional, default: float("inf")), limit the search to a certain depth, currently
 works only for breadth first search
- •post_process (optional, default: None), for forest only
- •facade (optional, default: None)
- •category (optional, default: None)

EXAMPLES:

A recursive set with no other information:

```
sage: f = lambda a: [a+3, a+5]
sage: C = RecursivelyEnumeratedSet([0], f)
sage: C
A recursively enumerated set (breadth first search)
sage: it = iter(C)
sage: [next(it) for _ in range(10)]
[0, 3, 5, 8, 10, 6, 9, 11, 13, 15]
```

A recursive set with a forest structure:

```
sage: f = lambda a: [2*a, 2*a+1]
sage: C = RecursivelyEnumeratedSet([1], f, structure='forest')
An enumerated set with a forest structure
sage: it = C.depth_first_search_iterator()
sage: [next(it) for _ in range(7)]
[1, 2, 4, 8, 16, 32, 64]
sage: it = C.breadth_first_search_iterator()
sage: [next(it) for _ in range(7)]
[1, 2, 3, 4, 5, 6, 7]
A recursive set given by a symmetric relation:
sage: f = lambda a: [a-1,a+1]
sage: C = RecursivelyEnumeratedSet([10, 15], f, structure='symmetric')
sage: C
A recursively enumerated set with a symmetric structure (breadth first search)
sage: it = iter(C)
sage: [next(it) for _ in range(7)]
[10, 15, 16, 9, 11, 14, 8]
A recursive set given by a graded relation:
sage: f = lambda a: [a+1, a+I]
sage: C = RecursivelyEnumeratedSet([0], f, structure='graded')
sage: C
A recursively enumerated set with a graded structure (breadth first search)
sage: it = iter(C)
sage: [next(it) for _ in range(7)]
[0, 1, I, I + 1, 2, 2*I, I + 2]
 Warning: If you do not set the good structure, you might obtain bad results, like elements generated twice:
 sage: f = lambda a: [a-1,a+1]
 sage: C = RecursivelyEnumeratedSet([0], f, structure='graded')
 sage: it = iter(C)
 sage: [next(it) for _ in range(7)]
 [0, 1, -1, 0, 2, -2, 1]
TESTS:
The succesors method is an attribute:
sage: R = RecursivelyEnumeratedSet([1], lambda x: [x+1, x-1])
sage: R.successors(4)
[5, 3]
sage: C = RecursivelyEnumeratedSet((1, 2, 3), factor)
sage: C.successors
<function factor at ...>
sage: C._seeds
(1, 2, 3)
```

class sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_generic

A generic recursively enumerated set.

Bases: sage.structure.parent.Parent

For more information, see RecursivelyEnumeratedSet().

EXAMPLES:

```
sage: f = lambda a:[a+1]
```

Different structure for the sets:

```
sage: RecursivelyEnumeratedSet([0], f, structure=None)
A recursively enumerated set (breadth first search)
sage: RecursivelyEnumeratedSet([0], f, structure='graded')
A recursively enumerated set with a graded structure (breadth first search)
sage: RecursivelyEnumeratedSet([0], f, structure='symmetric')
A recursively enumerated set with a symmetric structure (breadth first search)
sage: RecursivelyEnumeratedSet([0], f, structure='forest')
An enumerated set with a forest structure
```

Different default enumeration algorithms:

```
sage: RecursivelyEnumeratedSet([0], f, enumeration='breadth')
A recursively enumerated set (breadth first search)
sage: RecursivelyEnumeratedSet([0], f, enumeration='naive')
A recursively enumerated set (naive search)
sage: RecursivelyEnumeratedSet([0], f, enumeration='depth')
A recursively enumerated set (depth first search)
```

breadth_first_search_iterator(max_depth=None)

Iterate on the elements of self (breadth first).

This code remembers every elements generated.

INPUT:

•max_depth - (Default: None) specifies the maximal depth to which elements are computed; if None, the value of self._max_depth is used

EXAMPLES:

```
sage: f = lambda a: [a+3, a+5]
sage: C = RecursivelyEnumeratedSet([0], f)
sage: it = C.breadth_first_search_iterator()
sage: [next(it) for _ in range(10)]
[0, 3, 5, 8, 10, 6, 9, 11, 13, 15]
```

depth_first_search_iterator()

Iterate on the elements of self (depth first).

This code remembers every elements generated.

See Wikipedia article Depth-first_search.

EXAMPLES:

```
sage: f = lambda a: [a+3, a+5]
sage: C = RecursivelyEnumeratedSet([0], f)
sage: it = C.depth_first_search_iterator()
sage: [next(it) for _ in range(10)]
[0, 5, 10, 15, 20, 25, 30, 35, 40, 45]
```

elements_of_depth_iterator(depth)

Iterate over the elements of self of given depth.

An element of depth n can be obtained applying n times the successor function to a seed.

```
INPUT:
       •depth - integer
    OUTPUT:
    An iterator.
    EXAMPLES:
    sage: f = lambda a: [a-1, a+1]
    sage: S = RecursivelyEnumeratedSet([5, 10], f, structure='symmetric')
    sage: it = S.elements_of_depth_iterator(2)
    sage: sorted(it)
    [3, 7, 8, 12]
graded component (depth)
    Return the graded component of given depth.
    This method caches each lower graded component.
    A graded component is a set of elements of the same depth where the depth of an element is its minimal
    distance to a root.
    INPUT:
       •depth - integer
    OUTPUT:
    A set.
    EXAMPLES:
    sage: f = lambda a: [a+3, a+5]
    sage: C = RecursivelyEnumeratedSet([0], f)
    sage: C.graded_component(0)
    Traceback (most recent call last):
    NotImplementedError: graded_component_iterator method currently implemented only for graded
    When the structure is symmetric:
    sage: f = lambda a: [a-1,a+1]
    sage: C = RecursivelyEnumeratedSet([10, 15], f, structure='symmetric')
    sage: for i in range(5): sorted(C.graded_component(i))
    [10, 15]
    [9, 11, 14, 16]
    [8, 12, 13, 17]
    [7, 18]
    [6, 19]
    When the structure is graded:
    sage: f = lambda a: [a+1, a+I]
    sage: C = RecursivelyEnumeratedSet([0], f, structure='graded')
    sage: for i in range(5): sorted(C.graded_component(i))
    [0]
    [I, 1]
    [2*I, I + 1, 2]
    [3*I, 2*I + 1, I + 2, 3]
```

[4*I, 3*I + 1, 2*I + 2, I + 3, 4]

```
graded_component_iterator()
         Iterate over the graded components of self.
         A graded component is a set of elements of the same depth.
         It is currently implemented only for herited classes.
         OUTPUT:
         An iterator of sets.
         EXAMPLES:
         sage: f = lambda a: [a+3, a+5]
         sage: C = RecursivelyEnumeratedSet([0], f)
         sage: it = C.graded_component_iterator()
                                                       # todo: not implemented
     naive_search_iterator()
         Iterate on the elements of self (in no particular order).
         This code remembers every elements generated.
         TESTS:
         We compute all the permutations of 3:
         sage: seeds = [Permutation([1,2,3])]
         sage: succ = attrcall("permutohedron_succ")
         sage: R = RecursivelyEnumeratedSet(seeds, succ)
         sage: list(R.naive_search_iterator())
         [[1, 2, 3], [2, 1, 3], [1, 3, 2], [2, 3, 1], [3, 2, 1], [3, 1, 2]]
     seeds()
         Return an iterable over the seeds of self.
         EXAMPLES:
         sage: R = RecursivelyEnumeratedSet([1], lambda x: [x+1, x-1])
         sage: R.seeds()
         [1]
     successors
class sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_graded
     Bases: sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_generic
     Generic tool for constructing ideals of a graded relation.
     INPUT:
        •seeds – list (or iterable) of hashable objects
        •successors – function (or callable) returning a list (or iterable)
        •enumeration - 'depth', 'breadth' or None (default: None)
        •max_depth - integer (default: float ("inf"))
     EXAMPLES:
     sage: f = lambda \ a: [(a[0]+1,a[1]), (a[0],a[1]+1)]
     sage: C = RecursivelyEnumeratedSet([(0,0)], f, structure='graded', max_depth=3)
     A recursively enumerated set with a graded structure (breadth first search)
     sage: sorted(C)
```

```
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0), (2, 1), (3, 0)]
```

breadth_first_search_iterator(max_depth=None)

Iterate on the elements of self (breadth first).

This iterator make use of the graded structure by remembering only the elements of the current depth.

INPUT:

•max_depth - (Default: None) Specifies the maximal depth to which elements are computed. If None, the value of self._max_depth is used.

EXAMPLES:

```
sage: f = lambda a: [(a[0]+1,a[1]), (a[0],a[1]+1)]
sage: C = RecursivelyEnumeratedSet([(0,0)], f, structure='graded')
sage: it = C.breadth_first_search_iterator(max_depth=3)
sage: list(it)
[(0, 0), (0, 1), (1, 0), (2, 0), (1, 1),
  (0, 2), (3, 0), (1, 2), (0, 3), (2, 1)]
```

graded_component_iterator()

Iterate over the graded components of self.

A graded component is a set of elements of the same depth.

The algorithm remembers only the current graded component generated since the structure is graded.

OUTPUT:

An iterator of sets.

EXAMPLES:

```
sage: f = lambda a: [(a[0]+1,a[1]), (a[0],a[1]+1)]
sage: C = RecursivelyEnumeratedSet([(0,0)], f, structure='graded', max_depth=3)
sage: it = C.graded_component_iterator()
sage: for _ in range(4): sorted(next(it))
[(0, 0)]
[(0, 1), (1, 0)]
[(0, 2), (1, 1), (2, 0)]
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

class sage.sets.recursively enumerated set.RecursivelyEnumeratedSet symmetric

Bases: sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_generic

Generic tool for constructing ideals of a symmetric relation.

INPUT:

- •seeds list (or iterable) of hashable objects
- •successors function (or callable) returning a list (or iterable)
- •enumeration 'depth', 'breadth' or None (default: None)
- •max_depth integer (default: float ("inf"))

EXAMPLES:

```
sage: f = lambda a: [a-1,a+1]
sage: C = RecursivelyEnumeratedSet([0], f, structure='symmetric')
sage: C
A recursively enumerated set with a symmetric structure (breadth first search)
```

```
sage: it = iter(C)
sage: [next(it) for _ in range(7)]
[0, 1, -1, 2, -2, 3, -3]
TESTS:
Do not use lambda functions for saving purposes:
sage: f = lambda a: [a-1,a+1]
sage: C = RecursivelyEnumeratedSet([0], f, structure='symmetric')
sage: loads(dumps(C))
Traceback (most recent call last):
PicklingError: Can't pickle <type 'function' >: attribute lookup __builtin__.function failed
This works in the command line but apparently not as a doctest:
sage: def f(a): return [a-1,a+1]
sage: C = RecursivelyEnumeratedSet([0], f, structure='symmetric')
sage: loads(dumps(C))
Traceback (most recent call last):
PicklingError: Can't pickle <type 'function' >: attribute lookup __builtin__.function failed
```

breadth_first_search_iterator(max_depth=None)

Iterate on the elements of self (breadth first).

INPUT:

•max_depth - (Default: None) specifies the maximal depth to which elements are computed; if None, the value of self._max_depth is used

Note: It should be slower than the other one since it must generates the whole graded component before yielding the first element of each graded component. It is used for test only.

```
EXAMPLES:
```

```
sage: f = lambda a: [(a[0]+1,a[1]), (a[0],a[1]+1)]
sage: C = RecursivelyEnumeratedSet([(0,0)], f, structure='graded')
sage: it = C._breadth_first_search_iterator_from_graded_component_iterator(max_depth=3)
sage: list(it)
[(0, 0), (0, 1), (1, 0), (2, 0), (1, 1), (0, 2)]
```

This iterator is used by default for symmetric structure:

```
sage: f = lambda a: [a-1,a+1]
sage: S = RecursivelyEnumeratedSet([10], f, structure='symmetric')
sage: it = iter(S)
sage: [next(it) for _ in range(7)]
[10, 9, 11, 8, 12, 13, 7]
```

graded_component_iterator()

Iterate over the graded components of self.

A graded component is a set of elements of the same depth.

The enumeration remembers only the last two graded components generated since the structure is symmetric.

OUTPUT:

An iterator of sets.

```
EXAMPLES:
```

```
sage: f = lambda a: [a-1, a+1]
sage: S = RecursivelyEnumeratedSet([10], f, structure='symmetric')
sage: it = S.graded_component_iterator()
sage: [sorted(next(it)) for _ in range(5)]
[[10], [9, 11], [8, 12], [7, 13], [6, 14]]
Starting with two generators:
sage: f = lambda a: [a-1, a+1]
sage: S = RecursivelyEnumeratedSet([5, 10], f, structure='symmetric')
sage: it = S.graded_component_iterator()
sage: [sorted(next(it)) for _ in range(5)]
[[5, 10], [4, 6, 9, 11], [3, 7, 8, 12], [2, 13], [1, 14]]
Gaussian integers:
sage: f = lambda a: [a+1, a+I]
sage: S = RecursivelyEnumeratedSet([0], f, structure='symmetric')
sage: it = S.graded_component_iterator()
sage: [sorted(next(it)) for _ in range(7)]
[[0],
 [I, 1],
 [2*I, I + 1, 2],
 [3*I, 2*I + 1, I + 2, 3],
```

[4*I, 3*I + 1, 2*I + 2, I + 3, 4],

[5*I, 4*I + 1, 3*I + 2, 2*I + 3, I + 4, 5],

[6*I, 5*I + 1, 4*I + 2, 3*I + 3, 2*I + 4, I + 5, 6]]

MAPS BETWEEN FINITE SETS

This module implements parents modeling the set of all maps between two finite sets. At the user level, any such parent should be constructed using the factory class FiniteSetMaps which properly selects which of its subclasses to use.

AUTHORS:

```
· Florent Hivert
class sage.sets.finite_set_maps.FiniteSetEndoMaps_N (n, action, category=None)
     Bases: sage.sets.finite_set_maps.FiniteSetMaps_MN
     The sets of all maps from \{1, 2, ..., n\} to itself
     Users should use the factory class FiniteSetMaps to create instances of this class.
     INPUT:
         •n – an integer.
         •category - the category in which the sets of maps is constructed. It must be a sub-category of
         FiniteMonoids() which is the default value.
     Element
         alias of FiniteSetEndoMap_N
     an_element()
         Returns a map in self
         EXAMPLES:
          sage: M = FiniteSetMaps(4)
          sage: M.an_element()
          [3, 2, 1, 0]
     one()
         EXAMPLES:
          sage: M = FiniteSetMaps(4)
```

```
class sage.sets.finite_set_maps.FiniteSetEndoMaps_Set (domain, action, category=None)
```

Bases: sage.sets.finite_set_maps.FiniteSetMaps_Set, sage.sets.finite_set_maps.FiniteSetEnd

The sets of all maps from a set to itself

sage: M.one()
[0, 1, 2, 3]

Users should use the factory class FiniteSetMaps to create instances of this class.

INPUT:

- •domain an object in the category FiniteSets().
- •category the category in which the sets of maps is constructed. It must be a sub-category of FiniteMonoids () which is the default value.

Element

alias of FiniteSetEndoMap_Set

```
class sage.sets.finite_set_maps.FiniteSetMaps
```

```
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
```

Maps between finite sets

Constructs the set of all maps between two sets. The sets can be given using any of the three following ways:

1.an object in the category Sets ().

- 2.a finite iterable. In this case, an object of the class FiniteEnumeratedSet is constructed from the iterable.
- 3.an integer n designing the set $\{1, 2, \dots, n\}$. In this case an object of the class IntegerRange is constructed.

INPUT:

- •domain a set, finite iterable, or integer.
- •codomain a set, finite iterable, integer, or None (default). In this last case, the maps are endo-maps of the domain.
- •action "left" (default) or "right". The side where the maps act on the domain. This is used in particular to define the meaning of the product (composition) of two maps.
- •category the category in which the sets of maps is constructed. By default, this is FiniteMonoids() if the domain and codomain coincide, and FiniteEnumeratedSets() otherwise.

OUTPUT:

an instance of a subclass of FiniteSetMaps modeling the set of all maps between domain and codomain.

EXAMPLES:

We construct the set M of all maps from $\{a, b\}$ to $\{3, 4, 5\}$:

```
sage: M = FiniteSetMaps(["a", "b"], [3, 4, 5]); M
Maps from \{'a', 'b'\} to \{3, 4, 5\}
sage: M.cardinality()
sage: M.domain()
{'a', 'b'}
sage: M.codomain()
{3, 4, 5}
sage: for f in M: print f
map: a -> 3, b -> 3
map: a -> 3, b -> 4
map: a -> 3, b -> 5
map: a -> 4, b -> 3
map: a -> 4, b -> 4
map: a -> 4, b -> 5
map: a -> 5, b -> 3
map: a -> 5, b -> 4
map: a -> 5, b -> 5
```

Elements can be constructed from functions and dictionaries:

```
sage: M(lambda c: ord(c)-94)
map: a -> 3, b -> 4

sage: M.from_dict({'a':3, 'b':5})
map: a -> 3, b -> 5
```

If the domain is equal to the codomain, then maps can be composed:

```
sage: M = FiniteSetMaps([1, 2, 3])
sage: f = M.from_dict({1:2, 2:1, 3:3}); f
map: 1 -> 2, 2 -> 1, 3 -> 3
sage: g = M.from_dict({1:2, 2:3, 3:1}); g
map: 1 -> 2, 2 -> 3, 3 -> 1

sage: f * g
map: 1 -> 1, 2 -> 3, 3 -> 2
```

This makes M into a monoid:

```
sage: M.category()
Category of finite monoids
sage: M.one()
map: 1 -> 1, 2 -> 2, 3 -> 3
```

By default, composition is from right to left, which corresponds to an action on the left. If one specifies action to right, then the composition is from left to right:

```
sage: M = FiniteSetMaps([1, 2, 3], action = 'right')
sage: f = M.from_dict({1:2, 2:1, 3:3})
sage: g = M.from_dict({1:2, 2:3, 3:1})
sage: f * g
map: 1 -> 3, 2 -> 2, 3 -> 1
```

If the domains and codomains are both of the form $\{0, \dots\}$, then one can use the shortcut:

```
sage: M = FiniteSetMaps(2,3); M
Maps from {0, 1} to {0, 1, 2}
sage: M.cardinality()
9
```

For a compact notation, the elements are then printed as lists [f(i), i = 0, ...]:

```
sage: list(M)
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
```

TESTS:

```
sage: TestSuite(FiniteSetMaps(0)).run()
sage: TestSuite(FiniteSetMaps(0, 2)).run()
sage: TestSuite(FiniteSetMaps(2, 0)).run()
sage: TestSuite(FiniteSetMaps([], [])).run()
sage: TestSuite(FiniteSetMaps([1, 2], [])).run()
sage: TestSuite(FiniteSetMaps([], [1, 2])).run()
```

cardinality()

The cardinality of self

```
sage: FiniteSetMaps(4, 3).cardinality()
          81
class sage.sets.finite_set_maps.FiniteSetMaps_MN (m, n, category=None)
     Bases: sage.sets.finite_set_maps.FiniteSetMaps
     The set of all maps from \{1, 2, \dots, m\} to \{1, 2, \dots, n\}.
     Users should use the factory class FiniteSetMaps to create instances of this class.
     INPUT:
         •m, n – integers
         •category - the category in which the sets of maps is constructed. It must be a sub-category of
         FiniteEnumeratedSets() which is the default value.
     Element
          alias of FiniteSetMap_MN
     an element()
          Returns a map in self
          EXAMPLES:
          sage: M = FiniteSetMaps(4, 2)
          sage: M.an_element()
          [0, 0, 0, 0]
          sage: M = FiniteSetMaps(0, 0)
          sage: M.an_element()
          An exception EmptySetError is raised if this set is empty, that is if the codomain is empty and the
          domain is not.
              sage: M = FiniteSetMaps(4, 0) sage: M.cardinality() 0 sage: M.an_element() Traceback (most
              recent call last): ... EmptySetError
     codomain()
          The codomain of self
          EXAMPLES:
          sage: FiniteSetMaps(3,2).codomain()
          {0, 1}
     domain()
         The domain of self
         EXAMPLES:
          sage: FiniteSetMaps(3,2).domain()
          \{0, 1, 2\}
class sage.sets.finite_set_maps.FiniteSetMaps_Set (domain, codomain, category=None)
     Bases: sage.sets.finite_set_maps.FiniteSetMaps_MN
     The sets of all maps between two sets
     Users should use the factory class FiniteSetMaps to create instances of this class.
     INPUT:
```

- •domain an object in the category FiniteSets().
- •codomain an object in the category FiniteSets ().
- •category the category in which the sets of maps is constructed. It must be a sub-category of FiniteEnumeratedSets() which is the default value.

Element

```
alias of FiniteSetMap_Set
```

codomain()

The codomain of self

EXAMPLES:

```
sage: FiniteSetMaps(["a", "b"], [3, 4, 5]).codomain()
{3, 4, 5}
```

domain()

The domain of self

EXAMPLES:

```
sage: FiniteSetMaps(["a", "b"], [3, 4, 5]).domain()
{'a', 'b'}
```

from_dict(d)

Create a map from a dictionary

```
sage: M = FiniteSetMaps(["a", "b"], [3, 4, 5])
sage: M.from_dict({"a": 4, "b": 3})
map: a -> 4, b -> 3
```

DATA STRUCTURES FOR MAPS BETWEEN FINITE SETS

Data structures for maps between finite sets

This module implements several fast Cython data structures for maps between two finite set. Those classes are not intended to be used directly. Instead, such a map should be constructed via its parent, using the class FiniteSetMaps.

EXAMPLES:

To create a map between two sets, one first creates the set of such maps:

```
sage: M = FiniteSetMaps(["a", "b"], [3, 4, 5])
```

The map can then be constructed either from a function:

```
sage: f1 = M(lambda c: ord(c)-94); f1 map: a -> 3, b -> 4
```

or from a dictionary:

```
sage: f2 = M.from_dict({'a':3, 'b':4}); f2
map: a -> 3, b -> 4
```

The two created maps are equal:

```
sage: f1 == f2
True
```

Internally, maps are represented as the list of the ranks of the images f(x) in the co-domain, in the order of the domain:

```
sage: list(f2)
[0, 1]
```

A third fast way to create a map it to use such a list. it should be kept for internal use:

```
sage: f3 = M._from_list_([0, 1]); f3
map: a -> 3, b -> 4
sage: f1 == f3
True
```

Florent Hivert

```
class sage.sets.finite_set_map_cy.FiniteSetEndoMap_N
     Bases: sage.sets.finite_set_map_cy.FiniteSetMap_MN
     Maps from range (n) to itself.
     See Also:
     FiniteSetMap MN for assumptions on the parent
     sage: fs = FiniteSetMaps(3)([1, 0, 2])
     sage: TestSuite(fs).run()
class sage.sets.finite_set_map_cy.FiniteSetEndoMap_Set
     Bases: sage.sets.finite_set_map_cy.FiniteSetMap_Set
     Maps from a set to itself
     See Also:
     FiniteSetMap_Set for assumptions on the parent
     TESTS:
     sage: F = FiniteSetMaps(["a", "b", "c"])
     sage: f = F.from_dict({"a": "b", "b": "a", "c": "b"}); f
     map: a \rightarrow b, b \rightarrow a, c \rightarrow b
     sage: TestSuite(f).run()
class sage.sets.finite_set_map_cy.FiniteSetMap_MN
     Bases: sage.structure.list_clone.ClonableIntArray
     Data structure for maps from range (m) to range (n).
     We assume that the parent given as argument is such that:
        •m is stored in self.parent()._m
        •n is stored in self.parent()._n
        •the domain is in self.parent().domain()
        •the codomain is in self.parent().codomain()
     check()
         Performs checks on self
         Check that self is a proper function and then calls parent.check_element(self) where
         parent is the parent of self.
         TESTS:
         sage: fs = FiniteSetMaps(3, 2)
         sage: for el in fs: el.check()
         sage: fs([1,1])
         Traceback (most recent call last):
         AssertionError: Wrong number of values
         sage: fs([0,0,2])
         Traceback (most recent call last):
         AssertionError: Wrong value self(2) = 2
```

```
codomain()
    Returns the codomain of self
    EXAMPLES:
    sage: FiniteSetMaps(4, 3)([1, 0, 2, 1]).codomain()
    {0, 1, 2}
domain()
    Returns the domain of self
    EXAMPLES:
    sage: FiniteSetMaps(4, 3)([1, 0, 2, 1]).domain()
    {0, 1, 2, 3}
fibers()
    Returns the fibers of self
    OUTPUT:
        a dictionary d such that d[y] is the set of all x in domain such that f(x) = y
    EXAMPLES:
    sage: FiniteSetMaps(4, 3)([1, 0, 2, 1]).fibers()
    \{0: \{1\}, 1: \{0, 3\}, 2: \{2\}\}\
    sage: F = FiniteSetMaps(["a", "b", "c"])
    sage: F.from_dict({"a": "b", "b": "a", "c": "b"}).fibers()
    {'a': {'b'}, 'b': {'a', 'c'}}
getimage(i)
    Returns the image of i by self
    INPUT:
       •i – any object.
    Note: if you need speed, please use instead _getimage()
    EXAMPLES:
    sage: fs = FiniteSetMaps(4, 3)([1, 0, 2, 1])
    sage: fs.getimage(0), fs.getimage(1), fs.getimage(2), fs.getimage(3)
    (1, 0, 2, 1)
image_set()
    Returns the image set of self
    EXAMPLES:
    sage: FiniteSetMaps(4, 3)([1, 0, 2, 1]).image_set()
    {0, 1, 2}
    sage: FiniteSetMaps(4, 3)([1, 0, 0, 1]).image_set()
    {0, 1}
items()
    The items of self
    Return the list of the ordered pairs (x, self(x))
    EXAMPLES:
```

```
sage: FiniteSetMaps(4, 3)([1, 0, 2, 1]).items()
[(0, 1), (1, 0), (2, 2), (3, 1)]

setimage(i,j)
Set the image of i as j in self
```

Warning: self must be mutable; otherwise an exception is raised.

INPUT:

•i, j-two object's

OUTPUT: None

Note: if you need speed, please use instead _setimage()

EXAMPLES:

class sage.sets.finite_set_map_cy.FiniteSetMap_Set

Bases: sage.sets.finite_set_map_cy.FiniteSetMap_MN

Data structure for maps

We assume that the parent given as argument is such that:

- •the domain is in parent.domain()
- •the codomain is in parent.codomain()
- $\ensuremath{\,^{\circ}}\xspace{\text{parent.}}\xspace_{\ensuremath{\text{m}}}\xspace$ contains the cardinality of the domain
- •parent._n contains the cardinality of the codomain
- •parent._unrank_domain and parent._rank_domain is a pair of reciprocal rank and unrank functions beween the domain and range (parent._m).
- •parent._unrank_codomain and parent._rank_codomain is a pair of reciprocal rank and unrank functions beween the codomain and range (parent._n).

classmethod from_dict (parent, d)

Creates a FiniteSetMap from a dictionary

```
Warning: no check is performed!
```

TESTS:

```
sage: from sage.sets.finite_set_map_cy import FiniteSetMap_Set_from_dict as from_dict
sage: F = FiniteSetMaps(["a", "b"], [3, 4, 5])
sage: f = from_dict(F.element_class, F, {"a": 3, "b": 5}); f.check(); f
```

```
map: a -> 3, b -> 5
sage: f.parent() is F
True
sage: f.is_immutable()
True
```

classmethod from_list (parent, lst)

TESTS:

Creates a FiniteSetMap from a list

```
Warning: no check is performed!
```

```
TESTS:
    sage: from sage.sets.finite_set_map_cy import FiniteSetMap_Set_from_list as from_list
    sage: F = FiniteSetMaps(["a", "b"], [3, 4, 5])
    sage: f = from_list(F.element_class, F, [0,2]); f.check(); f
    map: a -> 3, b -> 5
    sage: f.parent() is F
    sage: f.is_immutable()
    True
getimage(i)
    Returns the image of i by self
    INPUT:
       \bulleti - an int
    EXAMPLES:
    sage: F = FiniteSetMaps(["a", "b", "c", "d"], ["u", "v", "w"])
    sage: fs = F._from_list_([1, 0, 2, 1])
    sage: map(fs.getimage, ["a", "b", "c", "d"])
    ['v', 'u', 'w', 'v']
image_set()
    Returns the image set of self
    EXAMPLES:
    sage: F = FiniteSetMaps(["a", "b", "c"])
    sage: F.from_dict({"a": "b", "b": "a", "c": "b"}).image_set()
    {'a', 'b'}
    sage: F = FiniteSetMaps(["a", "b", "c"])
    sage: F(lambda x: "c").image_set()
    {'c'}
items()
    The items of self
    Return the list of the couple (x, self(x))
    EXAMPLES:
    sage: F = FiniteSetMaps(["a", "b", "c"])
    sage: F.from_dict({"a": "b", "b": "a", "c": "b"}).items()
    [('a', 'b'), ('b', 'a'), ('c', 'b')]
```

```
sage: all(F.from_dict(dict(f.items())) == f for f in F)
         True
    setimage(i, j)
         Set the image of i as j in self
          Warning: self must be mutable otherwise an exception is raised.
         INPUT:
           •i, j-two object's
         OUTPUT: None
         EXAMPLES:
         sage: F = FiniteSetMaps(["a", "b", "c", "d"], ["u", "v", "w"])
         sage: fs = F(lambda x: "v")
         sage: fs2 = copy(fs)
         sage: fs2.setimage("a", "w")
         sage: fs2
         map: a -> w, b -> v, c -> v, d -> v
         sage: with fs.clone() as fs3:
                  fs3.setimage("a", "u")
                   fs3.setimage("c", "w")
         . . .
         sage: fs3
         map: a -> u, b -> v, c -> w, d -> v
         TESTS:
         sage: with fs.clone() as fs3:
                 fs3.setimage("z", 2)
         Traceback (most recent call last):
         ValueError: 'z' is not in list
         sage: with fs.clone() as fs3:
                  fs3.setimage(1, 4)
         Traceback (most recent call last):
         ValueError: 1 is not in list
sage.sets.finite_set_map_cy.FiniteSetMap_Set_from_dict (cls, parent, d)
    Creates a FiniteSetMap from a dictionary
      Warning: no check is performed!
    TESTS:
    sage: from sage.sets.finite_set_map_cy import FiniteSetMap_Set_from_dict as from_dict
    sage: F = FiniteSetMaps(["a", "b"], [3, 4, 5])
    sage: f = from_dict(F.element_class, F, {"a": 3, "b": 5}); f.check(); f
    map: a -> 3, b -> 5
    sage: f.parent() is F
    True
    sage: f.is_immutable()
    True
```

```
sage.sets.finite_set_map_cy.FiniteSetMap_Set_from_list (cls, parent, lst)
Creates a FiniteSetMap from a list
```

```
Warning: no check is performed!
```

```
TESTS:
```

```
sage: from sage.sets.finite_set_map_cy import FiniteSetMap_Set_from_list as from_list
sage: F = FiniteSetMaps(["a", "b"], [3, 4, 5])
sage: f = from_list(F.element_class, F, [0,2]); f.check(); f
map: a -> 3, b -> 5
sage: f.parent() is F
True
sage: f.is_immutable()
True
```

sage.sets.finite_set_map_cy.fibers(f, domain)

Returns the fibers of the function f on the finite set domain

INPUT:

- •f a function or callable
- •domain a finite iterable

OUTPUT:

•a dictionary d such that d[y] is the set of all x in domain such that f(x) = y

EXAMPLES:

```
sage: from sage.sets.finite_set_map_cy import fibers, fibers_args
sage: fibers(lambda x: 1, [])
{}
sage: fibers(lambda x: x^2, [-1, 2, -3, 1, 3, 4])
{16: {4}, 1: {1, -1}, 4: {2}, 9: {3, -3}}
sage: fibers(lambda x: 1, [-1, 2, -3, 1, 3, 4])
{1: {1, 2, 3, 4, -3, -1}}
sage: fibers(lambda x: 1, [1,1,1])
{1: {1}}
```

See Also:

fibers_args () if one needs to pass extra arguments to f.

```
sage.sets.finite_set_map_cy.fibers_args (f, domain, *args, **opts)
```

Returns the fibers of the function ${\tt f}$ on the finite set ${\tt domain}$

It is the same as fibers () except that one can pass extra argument for f (with a small overhead)

```
sage: from sage.sets.finite_set_map_cy import fibers_args
sage: fibers_args(operator.pow, [-1, 2, -3, 1, 3, 4], 2)
{16: {4}, 1: {1, -1}, 4: {2}, 9: {3, -3}}
```

INTEGER RANGE

AUTHORS:

- Nicolas Borie (2010-03): First release.
- Florent Hivert (2010-03): Added a class factory + cardinality method.
- Vincent Delecroix (2012-02): add methods rank/unrank, make it complient with Python int.

```
class sage.sets.integer_range.IntegerRange
```

```
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
```

The class of Integer ranges

Returns an enumerated set containing an arithmetic progression of integers.

INPUT:

- •begin an integer, Infinity or -Infinity
- •end an integer, Infinity or -Infinity
- •step a non zero integer (default to 1)
- •middle_point an integer inside the set (default to None)

OUTPUT:

A parent in the category FiniteEnumeratedSets() or InfiniteEnumeratedSets() depending on the arguments defining self.

IntegerRange (i, j) returns the set of $\{i, i+1, i+2, \ldots, j-1\}$. start (!) defaults to 0. When step is given, it specifies the increment. The default increment is 1. IntegerRange allows begin and end to be infinite.

IntegerRange is designed to have similar interface Python range. However, whereas range accept and returns Python int, IntegerRange deals with Integer.

If middle_point is given, then the elements are generated starting from it, in a alternating way: $\{m, m + 1, m - 2, m + 2, m - 2 \dots\}$.

```
sage: list(IntegerRange(5))
[0, 1, 2, 3, 4]
sage: list(IntegerRange(2,5))
[2, 3, 4]
sage: I = IntegerRange(2,100,5); I
{2, 7, ..., 97}
sage: list(I)
```

```
[2, 7, 12, 17, 22, 27, 32, 37, 42, 47, 52, 57, 62, 67, 72, 77, 82, 87, 92, 97]
sage: I.category()
Category of facade finite enumerated sets
sage: I[1].parent()
Integer Ring
```

When begin and end are both finite, IntegerRange (begin, end, step) is the set whose list of elements is equivalent to the python construction range (begin, end, step):

```
sage: list(IntegerRange(4,105,3)) == range(4,105,3)
True
sage: list(IntegerRange(-54,13,12)) == range(-54,13,12)
True
```

Except for the type of the numbers:

```
sage: type(IntegerRange(-54,13,12)[0]), type(range(-54,13,12)[0])
(<type 'sage.rings.integer.Integer'>, <type 'int'>)
```

When begin is finite and end is +Infinity, self is the infinite arithmetic progression starting from the begin by step step:

```
sage: I = IntegerRange(54,Infinity,3); I
{54, 57, ...}
sage: I.category()
Category of facade infinite enumerated sets
sage: p = iter(I)
sage: (p.next(), p.next(), p.next(), p.next(), p.next(), p.next())
(54, 57, 60, 63, 66, 69)

sage: I = IntegerRange(54,-Infinity,-3); I
{54, 51, ...}
sage: I.category()
Category of facade infinite enumerated sets
sage: p = iter(I)
sage: (p.next(), p.next(), p.next(), p.next(), p.next(), p.next())
(54, 51, 48, 45, 42, 39)
```

When begin and end are both infinite, you will have to specify the extra argument middle_point. self is then defined by a point and a progression/regression setting by step. The enumeration is done this way: (let us call m the middle_point) $\{m, m + step, m - step, m + 2step, m - 2step, m + 3step, \dots\}$:

```
sage: I = IntegerRange(-Infinity,Infinity,37,-12); I
Integer progression containing -12 with increment 37 and bounded with -Infinity and +Infinity
sage: I.category()
Category of facade infinite enumerated sets
sage: -12 in I
True
sage: -15 in I
False
sage: p = iter(I)
sage: (p.next(), p.next(), p.next(), p.next(), p.next(), p.next(), p.next(), p.next())
(-12, 25, -49, 62, -86, 99, -123, 136)
```

It is also possible to use the argument middle_point for other cases, finite or infinite. The set will be the same as if you didn't give this extra argument but the enumeration will begin with this middle_point:

```
sage: I = IntegerRange(123,-12,-14); I
{123, 109, ..., -3}
sage: list(I)
```

```
[123, 109, 95, 81, 67, 53, 39, 25, 11, -3]

sage: J = IntegerRange(123,-12,-14,25); J

Integer progression containing 25 with increment -14 and bounded with 123 and -12

sage: list(J)

[25, 11, 39, -3, 53, 67, 81, 95, 109, 123]
```

Remember that, like for range, if you define a non empty set, begin is supposed to be included and end is supposed to be excluded. In the same way, when you define a set with a middle_point, the begin bound will be supposed to be included and the end bound supposed to be excluded:

```
sage: I = IntegerRange(-100,100,10,0)
sage: J = range(-100,100,10)
sage: 100 in I
False
sage: 100 in J
False
sage: -100 in I
True
sage: -100 in J
True
sage: list(I)
[0, 10, -10, 20, -20, 30, -30, 40, -40, 50, -50, 60, -60, 70, -70, 80, -80, 90, -90, -100]
```

Note: The input is normalized so that:

```
sage: IntegerRange(1, 6, 2) is IntegerRange(1, 7, 2)
True
sage: IntegerRange(1, 8, 3) is IntegerRange(1, 10, 3)
True
```

TESTS:

```
sage: # Some category automatic tests
sage: TestSuite(IntegerRange(2,100,3)).run()
sage: TestSuite(IntegerRange(564,-12,-46)).run()
sage: TestSuite(IntegerRange(2, Infinity, 3)).run()
sage: TestSuite(IntegerRange(732, -Infinity, -13)).run()
sage: TestSuite(IntegerRange(-Infinity, Infinity, 3, 2)).run()
sage: TestSuite(IntegerRange(56, Infinity, 12, 80)).run()
sage: TestSuite(IntegerRange(732,-12,-2743,732)).run()
sage: # 20 random tests: range and IntegerRange give the same set for finite cases
sage: for i in range(20):
          begin = Integer (randint (-300, 300))
          end = Integer (randint (-300,300))
          step = Integer (randint (-20, 20))
. . .
          if step == 0:
. . .
              step = Integer(1)
. . .
          assert list(IntegerRange(begin, end, step)) == range(begin, end, step)
sage: # 20 random tests: range and IntegerRange with middle point for finite cases
sage: for i in range(20):
. . .
          begin = Integer (randint (-300, 300))
          end = Integer (randint (-300, 300))
. . .
          step = Integer (randint (-15, 15))
. . .
          if step == 0:
              step = Integer(-3)
          I = IntegerRange(begin, end, step)
          if I.cardinality() == 0:
```

```
assert len(range(begin, end, step)) == 0
                                       else:
                                                 TestSuite(I).run()
                                                  L1 = list(IntegerRange(begin, end, step, I.an_element()))
                                                 L2 = range(begin, end, step)
             . . .
                                                 L1.sort()
             . . .
                                                 L2.sort()
                                                 assert L1 == L2
            Thanks to trac ticket #8543 empty integer range are allowed:
            sage: TestSuite(IntegerRange(0, 5, -1)).run()
            element class
                        alias of Integer
class sage.sets.integer_range.IntegerRangeEmpty(elements)

            A singleton class for empty integer ranges
            See IntegerRange for more details.
class sage.sets.integer_range.IntegerRangeFinite(begin, end, step=1)
            Bases: sage.sets.integer_range.IntegerRange
            The class of finite enumerated sets of integers defined by finite arithmetic progressions
            See IntegerRange for more details.
            cardinality()
                        Return the cardinality of self
                       EXAMPLES:
                        sage: IntegerRange(123,12,-4).cardinality()
                       sage: IntegerRange(-57,12,8).cardinality()
                        sage: IntegerRange(123,12,4).cardinality()
            rank(x)
                       EXAMPLES:
                        sage: I = IntegerRange (-57, 36, 8)
                        sage: I.rank(23)
                       10
                        sage: I.unrank(10)
                       sage: I.rank(22)
                       Traceback (most recent call last):
                       IndexError: 22 not in self
                        sage: I.rank(87)
                       Traceback (most recent call last):
                       IndexError: 87 not in self
            unrank (i)
                       Return the i-th elt of this integer range.
```

```
EXAMPLES:
         sage: I=IntegerRange(1,13,5)
         sage: I[0], I[1], I[2]
         (1, 6, 11)
         sage: I[3]
         Traceback (most recent call last):
         IndexError: out of range
         sage: I[-1]
         sage: I[-4]
         Traceback (most recent call last):
         IndexError: out of range
         sage: I = IntegerRange (13, 1, -1)
         sage: l = I.list()
         sage: [I[i] for i in xrange(I.cardinality())] == 1
         sage: 1.reverse()
         sage: [I[i] for i in xrange (-1, -I) cardinality (-1, -1) == 1
class sage.sets.integer range.IntegerRangeFromMiddle(begin,
                                                                     end.
                                                                            step=1,
                                                                                     mid-
                                                             dle\ point=1)
    Bases: sage.sets.integer range.IntegerRange
    The class of finite or infinite enumerated sets defined with an inside point, a progression and two limits.
    See IntegerRange for more details.
    next (elt)
         Return the next element of elt in self.
         EXAMPLES:
         sage: from sage.sets.integer_range import IntegerRangeFromMiddle
         sage: I = IntegerRangeFromMiddle(-100,100,10,0)
         sage: (I.next(0), I.next(10), I.next(-10), I.next(20), I.next(-100))
         (10, -10, 20, -20, None)
         sage: I = IntegerRangeFromMiddle(-Infinity, Infinity, 10, 0)
         sage: (I.next(0), I.next(10), I.next(-10), I.next(20), I.next(-100))
         (10, -10, 20, -20, 110)
class sage.sets.integer_range.IntegerRangeInfinite(begin, step=1)
    Bases: sage.sets.integer_range.IntegerRange
    The class of infinite enumerated sets of integers defined by infinite arithmetic progressions.
    See IntegerRange for more details.
    rank(x)
         EXAMPLES:
         sage: I = IntegerRange(-57, Infinity, 8)
         sage: I.rank(23)
         10
         sage: I.unrank(10)
         2.3
         sage: I.rank(22)
         Traceback (most recent call last):
```

```
IndexError: 22 not in self

unrank(i)
   Returns the i-th element of self.

EXAMPLES:
   sage: I = IntegerRange(-8, Infinity, 3)
   sage: I.unrank(1)
   -5
```

POSITIVE INTEGERS

```
Bases: sage.sets.integer_range.IntegerRangeInfinite
The enumerated set of positive integers. To fix the ideas, we mean \{1, 2, 3, 4, 5, \dots\}.
This class implements the set of positive integers, as an enumerated set (see InfiniteEnumeratedSets).
This set is an integer range set. The construction is therefore done by IntegerRange (see IntegerRange).
EXAMPLES:
sage: PP = PositiveIntegers()
sage: PP
Positive integers
sage: PP.cardinality()
+Infinity
sage: TestSuite(PP).run()
sage: PP.list()
Traceback (most recent call last):
NotImplementedError: infinite list
sage: it = iter(PP)
sage: (it.next(), it.next(), it.next(), it.next())
(1, 2, 3, 4, 5)
sage: PP.first()
TESTS:
sage: TestSuite(PositiveIntegers()).run()
an element()
    Returns an element of self.
    EXAMPLES:
    sage: PositiveIntegers().an_element()
    42
```

class sage.sets.positive_integers.PositiveIntegers

NON NEGATIVE INTEGERS

```
class sage.sets.non negative integers.NonNegativeIntegers(category=None)
    Bases:
                        sage.structure.unique_representation.UniqueRepresentation,
     sage.structure.parent.Parent
    The enumerated set of non negative integers.
    This class implements the set of non negative integers,
                                                                   an enumerated set (see
                                                                as
     InfiniteEnumeratedSets).
    EXAMPLES:
    sage: NN = NonNegativeIntegers()
    sage: NN
    Non negative integers
    sage: NN.cardinality()
    +Infinity
    sage: TestSuite(NN).run()
    sage: NN.list()
    Traceback (most recent call last):
    NotImplementedError: infinite list
    sage: NN.element_class
    <type 'sage.rings.integer.Integer'>
    sage: it = iter(NN)
    sage: [it.next(), it.next(), it.next(), it.next()]
     [0, 1, 2, 3, 4]
    sage: NN.first()
    Currently, this is just a "facade" parent; namely its elements are plain Sage Integers with Integer Ring
    as parent:
    sage: x = NN(15); type(x)
    <type 'sage.rings.integer.Integer'>
    sage: x.parent()
    Integer Ring
    sage: x+3
    18
    In a later version, there will be an option to specify whether the elements should have Integer Ring or Non
    negative integers as parent:
    sage: NN = NonNegativeIntegers(facade = False) # todo: not implemented
    sage: x = NN(5)
                                                      # todo: not implemented
```

sage: x.parent()
Non negative integers

todo: not implemented

```
This runs generic sanity checks on NN:
sage: TestSuite(NN).run()
TODO: do not use NN any more in the doctests for NonNegativeIntegers.
Element
    alias of Integer
an_element()
    EXAMPLES:
    sage: NonNegativeIntegers().an_element()
from_integer
    alias of Integer
next(0)
    EXAMPLES:
    sage: NN = NonNegativeIntegers()
    sage: NN.next(3)
some elements()
    EXAMPLES:
    sage: NonNegativeIntegers().some_elements()
    [0, 1, 3, 42]
unrank (rnk)
    EXAMPLES:
    sage: NN = NonNegativeIntegers()
    sage: NN.unrank(100)
    100
```

THE SET OF PRIME NUMBERS

AUTHORS:

- William Stein (2005): original version
- Florent Hivert (2009-11): adapted to the category framework. The following methods were removed:
 - cardinality, __len__, __iter__: provided by EnumeratedSets
 - __cmp__(self, other): __eq__ is provided by UniqueRepresentation and seems to do as good a job (all test pass)

```
class sage.sets.primes.Primes(proof)
```

Bases: sage.structure.parent.Set_generic, sage.structure.unique_representation.UniqueRepre

The set of prime numbers.

EXAMPLES:

```
sage: P = Primes(); P
Set of all prime numbers: 2, 3, 5, 7, ...
```

We show various operations on the set of prime numbers:

```
sage: P.cardinality()
+Infinity
sage: R = Primes()
sage: P == R
True
sage: 5 in P
True
sage: 100 in P
False
                      # note: this used to be a TypeError
sage: len(P)
Traceback (most recent call last):
NotImplementedError: infinite list
first()
    Returns the first prime number.
    EXAMPLES:
```

```
sage: P = Primes()
sage: P.first()
2
```

next(pr)

Returns the next prime number.

EXAMPLES:

```
sage: P = Primes()
sage: P.next(5)
7
```

$\mathtt{unrank}\,(n)$

Returns the n-th prime number.

EXAMPLES:: sage: P = Primes() sage: P.unrank(0) 2 sage: P.unrank(5) 13 sage: P.unrank(42) 191

TOTALLY ORDERED FINITE SETS

AUTHORS:

• Stepan Starosta (2012): Initial version

```
 \begin{array}{c} \textbf{class} \texttt{ sage.sets.totally\_ordered\_finite\_set.TotallyOrderedFiniteSet} (\textit{elements}, \textit{fa-cade=True}) \\ \textbf{Bases: } \texttt{ sage.sets.finite\_enumerated\_set.FiniteEnumeratedSet} \end{array}
```

Totally ordered finite set.

This is a finite enumerated set assuming that the elements are ordered based upon their rank (i.e. their position in the set).

INPUT:

- •elements A list of elements in the set
- •facade (default: True) if True, a facade is used; it should be set to False if the elements do not inherit from Element or if you want a funny order. See examples for more details.

See Also:

FiniteEnumeratedSet

EXAMPLES:

```
sage: S = TotallyOrderedFiniteSet([1,2,3])
sage: S
{1, 2, 3}
sage: S.cardinality()
3
```

By default, totally ordered finite set behaves as a facade:

```
sage: S(1).parent()
Integer Ring
```

It makes comparison fails when it is not the standard order:

```
sage: T1 = TotallyOrderedFiniteSet([3,2,5,1])
sage: T1(3) < T1(1)
False
sage: T2 = TotallyOrderedFiniteSet([3,var('x')])
sage: T2(3) < T2(var('x'))
3 < x</pre>
```

To make the above example work, you should set the argument facade to False in the constructor. In that case, the elements of the set have a dedicated class:

```
sage: A = TotallyOrderedFiniteSet([3,2,0,'a',7,(0,0),1], facade=False)
sage: A
{3, 2, 0, 'a', 7, (0, 0), 1}
sage: x = A.an_element()
sage: x
sage: x.parent()
{3, 2, 0, 'a', 7, (0, 0), 1}
sage: A(3) < A(2)
True
sage: A('a') < A(7)
True
sage: A(3) > A(2)
False
sage: A(1) < A(3)
False
sage: A(3) == A(3)
True
But then, the equality comparison is always False with elements outside of the set:
sage: A(1) == 1
False
sage: 1 == A(1)
False
sage: 'a' == A('a')
False
sage: A('a') == 'a'
False
and comparisons are comparisons of types:
sage: for e in [1,'a',(0, 0)]:
       f = A(e)
. . .
       print e == f,
. . .
        print cmp(e,f) == cmp(type(e),type(f)),
        print cmp(f,e) == cmp(type(f),type(e))
False True True
False True True
False True True
This behavior of comparison is the same as the one of Element.
Since trac ticket #16280, totally ordered sets support elements that do not inherit from
sage.structure.element.Element, whether they are facade or not:
sage: S = TotallyOrderedFiniteSet(['a','b'])
sage: S('a')
sage: S = TotallyOrderedFiniteSet(['a','b'], facade = False)
sage: S('a')
'a'
Multiple elements are automatically deleted:
sage: TotallyOrderedFiniteSet([1,1,2,1,2,2,5,4])
{1, 2, 5, 4}
Element
```

alias of TotallyOrderedFiniteSetElement

```
le(x, y)
         Return True if x \leq y for the order of self.
         EXAMPLES:
         sage: T = TotallyOrderedFiniteSet([1,3,2], facade=False)
         sage: T1, T3, T2 = T.list()
         sage: T.le(T1,T3)
         True
         sage: T.le(T3,T2)
         True
class sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSetElement (parent,
                                                                                    data)
     Bases: sage.structure.element.Element
    Element of a finite totally ordered set.
    EXAMPLES:
     sage: S = TotallyOrderedFiniteSet([2,7], facade=False)
     sage: x = S(2)
     sage: print x
     sage: x.parent()
```

{2, 7}

SUBSETS OF THE REAL LINE

This module contains subsets of the real line that can be constructed as the union of a finite set of open and closed intervals.

EXAMPLES:

```
sage: RealSet(0,1)
(0, 1)
sage: RealSet((0,1), [2,3])
(0, 1) + [2, 3]
sage: RealSet(-oo, oo)
(-oo, +oo)
```

Brackets must be balanced in Python, so the naive notation for half-open intervals does not work:

```
sage: RealSet([0,1))
Traceback (most recent call last):
...
SyntaxError: invalid syntax
```

Instead, you can use the following construction functions:

```
sage: RealSet.open_closed(0,1)
(0, 1]
sage: RealSet.closed_open(0,1)
[0, 1)
sage: RealSet.point(1/2)
{1/2}
sage: RealSet.unbounded_below_open(0)
(-oo, 0)
sage: RealSet.unbounded_below_closed(0)
(-oo, 0]
sage: RealSet.unbounded_above_open(1)
(1, +oo)
sage: RealSet.unbounded_above_closed(1)
[1, +oo)
```

• Volker Braun (2013-06-22): Rewrite class sage.sets.real_set.RealInterval (lower, lower_closed, upper, upper_closed, check=True) sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent A real interval You are not supposed to create RealInterval objects yourself. Always use RealSet instead. INPUT: •lower – real or minus infinity. The lower bound of the interval. •lower_closed - boolean. Whether the interval is closed at the lower bound. •upper – real or (plus) infinity. The upper bound of the interval. •upper_closed – boolean. Whether the interval is closed at the upper bound. •check – boolean keyword argument. Whether to check the other arguments for validity. **EXAMPLES:** sage: RealSet([0, oo]) Traceback (most recent call last): ValueError: interval cannot be closed at +oo closure() Return the closure **OUTPUT:** The closure as a new RealInterval **EXAMPLES:** sage: RealSet.open(0,1)[0].closure() [0, 1] sage: RealSet.open(-oo,1)[0].closure() (-oo, 1] sage: RealSet.open(0, oo)[0].closure() [0, +00)contains (x) Return whether x is contained in the interval INPUT: •x – a real number. **OUTPUT:** Boolean. **EXAMPLES:** sage: i = RealSet.open_closed(0,2)[0]; i (0, 2] sage: i.contains(0)

False

True

True

sage: i.contains(1)

sage: i.contains(2)

```
convex hull(other)
    Return the convex hull of the two intervals
    OUTPUT:
    The convex hull as a new RealInterval.
    EXAMPLES:
    sage: I1 = RealSet.open(0, 1)[0]; I1
    (0, 1)
    sage: I2 = RealSet.closed(1, 2)[0]; I2
    [1, 2]
    sage: I1.convex_hull(I2)
    (0, 2]
    sage: I2.convex_hull(I1)
    (0, 2]
    sage: I1.convex_hull(I2.interior())
    (0, 2)
    sage: I1.closure().convex_hull(I2.interior())
    [0, 2)
    sage: I1.closure().convex_hull(I2)
    [0, 2]
    sage: I3 = RealSet.closed(1/2, 3/2)[0]; I3
    [1/2, 3/2]
    sage: I1.convex_hull(I3)
    (0, 3/2]
element_class
    alias of LazyFieldElement
interior()
    Return the interior
    OUTPUT:
    The interior as a new RealInterval
    EXAMPLES:
    sage: RealSet.closed(0, 1)[0].interior()
    (0, 1)
    sage: RealSet.open_closed(-oo, 1)[0].interior()
    (-00, 1)
    sage: RealSet.closed_open(0, oo)[0].interior()
    (0, +00)
intersection (other)
    Return the intersection of the two intervals
    INPUT:
       •other - a RealInterval
    OUTPUT:
    The intersection as a new RealInterval
    EXAMPLES:
    sage: I1 = RealSet.open(0, 2)[0]; I1
    (0, 2)
    sage: I2 = RealSet.closed(1, 3)[0]; I2
    [1, 3]
```

```
sage: I1.intersection(I2)
[1, 2)
sage: I2.intersection(I1)
[1, 2)
sage: I1.closure().intersection(I2.interior())
(1, 2]
sage: I2.interior().intersection(I1.closure())
(1, 2]

sage: I3 = RealSet.closed(10, 11)[0]; I3
[10, 11]
sage: I1.intersection(I3)
(0, 0)
sage: I3.intersection(I1)
(0, 0)
```

is connected (other)

Test whether two intervals are connected

OUTPUT

Boolean. Whether the set-theoretic union of the two intervals has a single connected component.

EXAMPLES:

```
sage: I1 = RealSet.open(0, 1)[0]; I1
(0, 1)
sage: I2 = RealSet.closed(1, 2)[0]; I2
[1, 2]
sage: I1.is_connected(I2)
True
sage: I1.is_connected(I2.interior())
False
sage: I1.closure().is_connected(I2.interior())
sage: I2.is_connected(I1)
True
sage: I2.interior().is_connected(I1)
False
sage: I2.closure().is_connected(I1.interior())
sage: I3 = RealSet.closed(1/2, 3/2)[0]; I3
[1/2, 3/2]
sage: I1.is_connected(I3)
sage: I3.is_connected(I1)
True
```

is_empty()

Return whether the interval is empty

The normalized form of RealSet has all intervals non-empty, so this method usually returns False.

OUTPUT:

Boolean.

```
sage: I = RealSet(0, 1)[0]
sage: I.is_empty()
```

```
False
is_point()
    Return whether the interval consists of a single point
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: I = RealSet(0, 1)[0]
    sage: I.is_point()
    False
lower()
    Return the lower bound
    OUTPUT:
    The lower bound as it was originally specified.
    EXAMPLES:
    sage: I = RealSet(0, 1)[0]
    sage: I.lower()
    sage: I.upper()
lower_closed()
    Return whether the interval is open at the lower bound
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: I = RealSet.open_closed(0, 1)[0]; I
    (0, 1]
    sage: I.lower_closed()
    False
    sage: I.lower_open()
    True
    sage: I.upper_closed()
    sage: I.upper_open()
    False
lower_open()
    Return whether the interval is closed at the upper bound
    OUTPUT:
    Boolean.
    EXAMPLES:
```

sage: I = RealSet.open_closed(0, 1)[0]; I

(0, 1]

False

sage: I.lower_closed()

sage: I.lower_open()

```
True
    sage: I.upper_closed()
    True
    sage: I.upper_open()
    False
upper()
    Return the upper bound
    OUTPUT:
    The upper bound as it was originally specified.
    EXAMPLES:
    sage: I = RealSet(0, 1)[0]
    sage: I.lower()
    sage: I.upper()
upper_closed()
    Return whether the interval is closed at the lower bound
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: I = RealSet.open_closed(0, 1)[0]; I
    (0, 1]
    sage: I.lower_closed()
    False
    sage: I.lower_open()
    True
    sage: I.upper_closed()
    sage: I.upper_open()
    False
upper_open()
    Return whether the interval is closed at the upper bound
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: I = RealSet.open_closed(0, 1)[0]; I
    (0, 1]
    sage: I.lower_closed()
    False
    sage: I.lower_open()
    sage: I.upper_closed()
    sage: I.upper_open()
    False
```

A subset of the real line

INPUT:

Arguments defining a real set. Possibilities are either two real numbers to construct an open set or a list/tuple/iterable of intervals. The individual intervals can be specified by either a RealInterval, a tuple of two real numbers (constructing an open interval), or a list of two number (constructing a closed interval).

EXAMPLES:

```
sage: RealSet(0,1)  # open set from two numbers
(0, 1)
sage: i = RealSet(0,1)[0]
sage: RealSet(i)  # interval
(0, 1)
sage: RealSet(i, (3,4))  # tuple of two numbers = open set
(0, 1) + (3, 4)
sage: RealSet(i, [3,4])  # list of two numbers = closed set
(0, 1) + [3, 4]
```

an_element()

Return a point of the set

OUTPUT:

A real number. ValueError if the set is empty.

EXAMPLES:

```
sage: RealSet.open_closed(0, 1).an_element()
1
sage: RealSet(0, 1).an_element()
1/2
```

static are_pairwise_disjoint (*real_set_collection)

Test whether sets are pairwise disjoint

INPUT:

•*real_set_collection - a list/tuple/iterable of RealSet.

OUTPUT:

Boolean.

EXAMPLES:

```
sage: s1 = RealSet((0, 1), (2, 3))
sage: s2 = RealSet((1, 2))
sage: s3 = RealSet.point(3)
sage: RealSet.are_pairwise_disjoint(s1, s2, s3)
True
sage: RealSet.are_pairwise_disjoint(s1, s2, s3, [10,10])
True
sage: RealSet.are_pairwise_disjoint(s1, s2, s3, [-1, 1/2])
False
```

cardinality()

Return the cardinality of the subset of the real line.

OUTPUT:

Integer or infinity. The size of a discrete set is the number of points; the size of a real interval is Infinity.

```
EXAMPLES:
```

```
sage: RealSet([0, 0], [1, 1], [3, 3]).cardinality()
3
sage: RealSet(0,3).cardinality()
+Infinity
```

static closed (lower, upper)

Construct a closed interval

INPUT:

•lower, upper – two real numbers or infinity. They will be sorted if necessary.

OUTPUT:

A new RealSet.

EXAMPLES:

```
sage: RealSet.closed(1, 0)
[0, 1]
```

static closed_open (lower, upper)

Construct an half-open interval

INPUT:

•lower, upper – two real numbers or infinity. They will be sorted if necessary.

OUTPUT:

A new RealSet that is closed at the lower bound and open an the upper bound.

EXAMPLES:

```
sage: RealSet.closed_open(1, 0)
[0, 1)
```

complement()

Return the complement

OUTPUT:

The set-theoretic complement as a new RealSet.

```
sage: RealSet(0,1).complement()
(-oo, 0] + [1, +oo)

sage: s1 = RealSet(0,2) + RealSet.unbounded_above_closed(10); s1
(0, 2) + [10, +oo)
sage: s1.complement()
(-oo, 0] + [2, 10)

sage: s2 = RealSet(1,3) + RealSet.unbounded_below_closed(-10); s2
(-oo, -10] + (1, 3)
sage: s2.complement()
(-10, 1] + [3, +oo)
```

```
Return whether x is contained in the set
    INPUT:
       •x – a real number.
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: s = RealSet(0,2) + RealSet.unbounded_above_closed(10); s
    (0, 2) + [10, +00)
    sage: s.contains(1)
    True
    sage: s.contains(0)
    False
    sage: 10 in s
                    # syntactic sugar
    True
difference(*other)
    Return self with other subtracted
    INPUT:
       •other - a RealSet or data that defines one.
    OUTPUT:
    The set-theoretic difference of self with other removed as a new RealSet.
    EXAMPLES:
    sage: s1 = RealSet(0,2) + RealSet.unbounded_above_closed(10); s1
    (0, 2) + [10, +00)
    sage: s2 = RealSet(1,3) + RealSet.unbounded_below_closed(-10); s2
    (-00, -10] + (1, 3)
    sage: s1.difference(s2)
    (0, 1] + [10, +00)
    sage: s1 - s2 # syntactic sugar
    (0, 1] + [10, +00)
    sage: s2.difference(s1)
    (-00, -10] + [2, 3)
    sage: s2 - s1
                     # syntactic sugar
    (-00, -10] + [2, 3)
    sage: s1.difference(1,11)
    (0, 1] + [11, +00)
get_interval(i)
    Return the i-th connected component.
    Note that the intervals representing the real set are always normalized, see normalize().
    INPUT:
       •i – integer.
    OUTPUT:
    The i-th connected component as a RealInterval.
    EXAMPLES:
```

contains (x)

```
sage: s = RealSet(RealSet.open_closed(0,1), RealSet.closed_open(2,3))
    sage: s.get_interval(0)
    (0, 1]
    sage: s[0]
                  # shorthand
    (0, 1]
    sage: s.get_interval(1)
    [2, 3)
    sage: s[0] == s.get_interval(0)
    True
inf()
    Return the infimum
    OUTPUT:
    A real number or infinity.
    EXAMPLES:
    sage: s1 = RealSet(0,2) + RealSet.unbounded_above_closed(10); s1
    (0, 2) + [10, +00)
    sage: s1.inf()
    sage: s2 = RealSet(1,3) + RealSet.unbounded_below_closed(-10); s2
    (-00, -10] + (1, 3)
    sage: s2.inf()
    -Infinity
intersection(*other)
    Return the intersection of the two sets
    INPUT:
       •other - a RealSet or data that defines one.
    OUTPUT:
    The set-theoretic intersection as a new RealSet.
    EXAMPLES:
    sage: s1 = RealSet(0,2) + RealSet.unbounded_above_closed(10); s1
    (0, 2) + [10, +00)
    sage: s2 = RealSet(1,3) + RealSet.unbounded_below_closed(-10); s2
    (-00, -10] + (1, 3)
    sage: s1.intersection(s2)
    (1, 2)
    sage: s1 & s2 # syntactic sugar
    (1, 2)
    sage: s1 = RealSet((0, 1), (2, 3)); s1
    (0, 1) + (2, 3)
    sage: s2 = RealSet([0, 1], [2, 3]); s2
    [0, 1] + [2, 3]
    sage: s3 = RealSet([1, 2]); s3
    [1, 2]
    sage: s1.intersection(s2)
    (0, 1) + (2, 3)
    sage: s1.intersection(s3)
    { }
```

```
sage: s2.intersection(s3)
    \{1\} + \{2\}
is_disjoint_from(*other)
    Test whether the two sets are disjoint
    INPUT:
       •other - a RealSet or data defining one.
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: s1 = RealSet((0, 1), (2, 3)); s1
    (0, 1) + (2, 3)
    sage: s2 = RealSet([1, 2]); s2
    [1, 2]
    sage: s1.is_disjoint_from(s2)
    sage: s1.is_disjoint_from([1, 2])
    True
is_empty()
    Return whether the set is empty
    EXAMPLES:
    sage: RealSet(0, 1).is_empty()
    False
    sage: RealSet(0, 0).is_empty()
    True
is_included_in(*other)
    Tests interval inclusion
    INPUT:
       •*args - a RealSet or something that defines one.
    OUTPUT:
    Boolean.
    EXAMPLES:
    sage: I = RealSet((1,2))
    sage: J = RealSet((1,3))
    sage: K = RealSet((2,3))
    sage: I.is_included_in(J)
    sage: J.is_included_in(K)
    False
n_components()
    Return the number of connected components
    See also get_interval()
    EXAMPLES:
```

```
sage: s = RealSet(RealSet.open_closed(0,1), RealSet.closed_open(2,3))
    sage: s.n_components()
static normalize (intervals)
    Bring a collection of intervals into canonical form
    INPUT:
        •intervals – a list/tuple/iterable of intervals.
    OUTPUT:
    A tuple of intervals such that
        •they are sorted in ascending order (by lower bound)
        •there is a gap between each interval
        •all intervals are non-empty
    EXAMPLES:
    sage: i1 = RealSet((0, 1))[0]
    sage: i2 = RealSet([1, 2])[0]
    sage: i3 = RealSet((2, 3))[0]
    sage: RealSet.normalize([i1, i2, i3])
     ((0, 3),)
    sage: RealSet((0, 1), [1, 2], (2, 3))
    (0, 3)
    sage: RealSet((0, 1), (1, 2), (2, 3))
    (0, 1) + (1, 2) + (2, 3)
    sage: RealSet([0, 1], [2, 3])
    [0, 1] + [2, 3]
    sage: RealSet((0, 2), (1, 3))
    (0, 3)
    sage: RealSet(0,0)
    { }
static open (lower, upper)
    Construct an open interval
    INPUT:
        •lower, upper - two real numbers or infinity. They will be sorted if necessary.
    OUTPUT:
    A new RealSet.
    EXAMPLES:
    sage: RealSet.open(1, 0)
    (0, 1)
static open_closed (lower, upper)
    Construct a half-open interval
    INPUT:
        •lower, upper – two real numbers or infinity. They will be sorted if necessary.
```

```
OUTPUT:
    A new RealSet that is open at the lower bound and closed at the upper bound.
    EXAMPLES:
    sage: RealSet.open_closed(1, 0)
    (0, 1]
static point (p)
    Construct an interval containing a single point
    INPUT:
       •p – a real number.
    OUTPUT:
    A new RealSet.
    EXAMPLES:
    sage: RealSet.open(1, 0)
    (0, 1)
sup()
    Return the supremum
    OUTPUT:
    A real number or infinity.
    EXAMPLES:
    sage: s1 = RealSet(0,2) + RealSet.unbounded_above_closed(10); s1
    (0, 2) + [10, +00)
    sage: s1.sup()
    +Infinity
    sage: s2 = RealSet(1,3) + RealSet.unbounded_below_closed(-10); s2
    (-00, -10] + (1, 3)
    sage: s2.sup()
static unbounded_above_closed (bound)
    Construct a semi-infinite interval
    INPUT:
       •bound - a real number.
    OUTPUT:
    A new RealSet from the bound (including) to plus infinity.
    EXAMPLES:
    sage: RealSet.unbounded_above_closed(1)
    [1, +00)
static unbounded_above_open (bound)
    Construct a semi-infinite interval
    INPUT:
```

•bound – a real number.

```
OUTPUT:
    A new RealSet from the bound (excluding) to plus infinity.
    EXAMPLES:
    sage: RealSet.unbounded_above_open(1)
    (1, +00)
static unbounded_below_closed (bound)
    Construct a semi-infinite interval
    INPUT:
       •bound - a real number.
    OUTPUT:
    A new RealSet from minus infinity to the bound (including).
    EXAMPLES:
    sage: RealSet.unbounded_below_closed(1)
    (-00, 1]
static unbounded_below_open (bound)
    Construct a semi-infinite interval
    INPUT:
       •bound – a real number.
    OUTPUT:
    A new RealSet from minus infinity to the bound (excluding).
    EXAMPLES:
    sage: RealSet.unbounded_below_open(1)
    (-00, 1)
union(*other)
    Return the union of the two sets
    INPUT:
       •other - a RealSet or data that defines one.
    OUTPUT:
    The set-theoretic union as a new RealSet.
    EXAMPLES:
    sage: s1 = RealSet(0,2)
    sage: s2 = RealSet(1,3)
    sage: s1.union(s2)
    (0, 3)
    sage: s1.union(1,3)
    (0, 3)
    sage: s1 | s2 # syntactic sugar
    (0, 3)
    sage: s1 + s2 # syntactic sugar
```

(0, 3)

BASE CLASS FOR PARENT OBJECTS

Base class for parent objects

CLASS HIERARCHY:

```
SageObject
CategoryObject
Parent
```

A simple example of registering coercions:

```
sage: class A_class(Parent):
....: def __init__(self, name):
           Parent.__init__(self, name=name)

```

When implementing an element of a ring, one would typically provide the element class with _rmul_ and/or _lmul_ methods for the action of a base ring, and with _mul_ for the ring multiplication. However, prior to trac ticket #14249, it would have been necessary to additionally define a method _an_element_() for the parent. But now, the following example works:

```
sage: class MyElement(RingElement):
. . . . :
          def __init__(self, parent, x, y):
              RingElement.__init__(self, parent)
. . . . :
          def _mul_(self, other):
. . . . :
               return self
. . . . :
          def _rmul_(self, other):
. . . . :
. . . . :
               return self
. . . . :
          def _lmul_(self, other):
               return self
. . . . :
sage: class MyParent (Parent):
....: Element = MyElement
Now, we define
sage: P = MyParent(base=ZZ, category=Rings())
sage: a = P(1, 2)
sage: a*a is a
sage: a*2 is a
True
sage: 2*a is a
True
TESTS:
This came up in some subtle bug once:
sage: qp(2) + qap(3)
class sage.structure.parent.EltPair
     Bases: object
     short_repr()
class sage.structure.parent.Parent
     Bases: sage.structure.category_object.CategoryObject
     Base class for all parents.
```

sage: from sage.structure.element import RingElement

Parents are the Sage/mathematical analogues of container objects in computer science.

INPUT:

- •base An algebraic structure considered to be the "base" of this parent (e.g. the base field for a vector space).
- •category a category or list/tuple of categories. The category in which this parent lies (or list or tuple thereof). Since categories support more general super-categories, this should be the most specific category possible. If category is a list or tuple, a JoinCategory is created out of them. If category is not specified, the category will be guessed (see CategoryObject), but won't be used to inherit parent's or element's code from this category.
- •element_constructor A class or function that creates elements of this Parent given appropriate input (can also be filled in later with _populate_coercion_lists_())
- gens Generators for this object (can also be filled in later with _populate_generators_())
- •names Names of generators.
- •normalize Whether to standardize the names (remove punctuation, etc)
- •facade a parent, or tuple thereof, or True

If facade is specified, then Sets().Facade() is added to the categories of the parent. Furthermore, if facade is not True, the internal attribute _facade_for is set accordingly for use by Sets.Facade.ParentMethods.facade_for().

Internal invariants:

```
•self._element_init_pass_parent == guess_pass_parent(self, self._element_constructor) Ensures that __call__() passes down the parent properly to element constructor(). See trac ticket #5979.
```

Todo

Eventually, category should be Sets by default.

TESTS:

We check that the facade option is compatible with specifying categories as a tuple:

```
sage: class MyClass(Parent): pass
sage: P = MyClass(facade = ZZ, category = (Monoids(), CommutativeAdditiveMonoids()))
sage: P.category()
Join of Category of monoids and Category of commutative additive monoids and Category of facade
```

```
\_\_call\_\_(x=0, *args, **kwds)
```

This is the generic call method for all parents.

When called, it will find a map based on the Parent (or type) of x. If a coercion exists, it will always be chosen. This map will then be called (with the arguments and keywords if any).

By default this will dispatch as quickly as possible to _element_constructor_() though faster pathways are possible if so desired.

TESTS:

We check that the invariant:

```
self._element_init_pass_parent == guess_pass_parent(self, self._element_constructor)
```

is preserved (see trac ticket #5979):

```
sage: class MyParent(Parent):
    ....: def _element_constructor_(self, x):
                  print self, x
    . . . . :
                  return sage.structure.element.Element(parent = self)
    . . . . :
    . . . . :
             def _repr_(self):
                  return "my_parent"
    . . . . :
    sage: my_parent = MyParent()
    sage: x = my_parent("bla")
    my_parent bla
    sage: x.parent()
                             # indirect doctest
    my_parent
    sage: x = my_parent() # shouldn't this one raise an error?
    mv parent 0
    sage: x = my_parent(3) # todo: not implemented why does this one fail???
    my_parent 3
                                              action\_list=[],
_populate_coercion_lists_(coerce_list=| |,
                                                               convert_list= | ,
                                                                                em-
                              bedding=None,
                                                 convert_method_name=None,
                                                                                ele-
                              ment_constructor=None,
                                                       init_no_parent=None,
                                                                             unpick-
                              ling=False)
```

ling=False)
This function allows one to specify coercions, actions, conversions and embeddings involving this parent.

IT SHOULD ONLY BE CALLED DURING THE __INIT__ method, often at the end.

INPUT:

- •coerce_list a list of coercion Morphisms to self and parents with canonical coercions to self
- •action list a list of actions on and by self
- •convert_list a list of conversion Maps to self and parents with conversions to self
- •embedding a single Morphism from self
- •convert_method_name a name to look for that other elements can implement to create elements of self (e.g. _integer_)
- •element_constructor A callable object used by the __call__ method to construct new elements. Typically the element class or a bound method (defaults to self._element_constructor_).
- •init_no_parent if True omit passing self in as the first argument of element_constructor for conversion. This is useful if parents are unique, or element_constructor is a bound method (this latter case can be detected automatically).

___mul___(x)

This is a multiplication method that more or less directly calls another attribute _mul_ (single underscore). This is because __mul_ can not be implemented via inheritance from the parent methods of the category, but _mul_ can be inherited. This is, e.g., used when creating twosided ideals of matrix algebras. See trac ticket #7797.

EXAMPLE:

```
sage: MS = MatrixSpace(QQ,2,2)
```

This matrix space is in fact an algebra, and in particular it is a ring, from the point of view of categories:

```
sage: MS.category()
Category of algebras over quotient fields
sage: MS in Rings()
True
```

However, its class does not inherit from the base class Ring:

```
sage: isinstance(MS,Ring)
False
```

Its _mul_ method is inherited from the category, and can be used to create a left or right ideal:

```
sage: MS._mul_.__module__
'sage.categories.rings'
sage: MS*MS.1 # indirect doctest
Left Ideal
  [0 1]
  [0 0]
of Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: MS*[MS.1,2]
Left Ideal
  [0 1]
  [0 0],
  [2 0]
  [0 2]
of Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: MS.1*MS
Right Ideal
  [0 1]
  [0 0]
of Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: [MS.1,2] *MS
Right Ideal
(
  [0 1]
  [0 0],
  [2 0]
  [0 2]
 of Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

$__contains__(x)$

True if there is an element of self that is equal to x under ==, or if x is already an element of self. Also, True in other cases involving the Symbolic Ring, which is handled specially.

For many structures we test this by using $__call__()$ and then testing equality between x and the result.

The Symbolic Ring is treated differently because it is ultra-permissive about letting other rings coerce in, but ultra-strict about doing comparisons.

```
sage: 2 in Integers(7)
True
sage: 2 in ZZ
True
sage: Integers(7)(3) in ZZ
True
```

```
sage: 3/1 in ZZ
True
sage: 5 in QQ
True
sage: I in RR
False
sage: SR(2) in ZZ
sage: RIF(1, 2) in RIF
sage: pi in RIF # there is no element of RIF equal to pi
sage: sqrt(2) in CC
True
sage: pi in RR
True
sage: pi in CC
sage: pi in RDF
True
sage: pi in CDF
True
```

TESTS:

Check that trac ticket #13824 is fixed:

```
sage: 4/3 in GF(3)
False
sage: 15/50 in GF(25, 'a')
False
sage: 7/4 in Integers(4)
False
sage: 15/36 in Integers(6)
False
```

$_{coerce_map_from_(S)}$

Override this method to specify coercions beyond those specified in coerce_list.

If no such coercion exists, return None or False. Otherwise, it may return either an actual Map to use for the coercion, a callable (in which case it will be wrapped in a Map), or True (in which case a generic map will be provided).

convert map from (S)

Override this method to provide additional conversions beyond those given in convert_list.

This function is called after coercions are attempted. If there is a coercion morphism in the opposite direction, one should consider adding a section method to that.

This MUST return a Map from S to self, or None. If None is returned then a generic map will be provided.

```
_get_action_(S, op, self_on_left)
```

Override this method to provide an action of self on S or S on self beyond what was specified in action_list.

This must return an action which accepts an element of self and an element of S (in the order specified by self_on_left).

```
_an_element_()
```

Returns an element of self. Want it in sufficient generality that poorly-written functions won't work when they're not supposed to. This is cached so doesn't have to be super fast.

EXAMPLES:

```
sage: QQ._an_element_()
1/2
sage: ZZ['x,y,z']._an_element_()
x
```

TESTS:

Since Parent comes before the parent classes provided by categories in the hierarchy of classes, we make sure that this default implementation of _an_element_() does not override some provided by the categories. Eventually, this default implementation should be moved into the categories to avoid this workaround:

```
sage: S = FiniteEnumeratedSet([1,2,3])
sage: S.category()
Category of facade finite enumerated sets
sage: super(Parent, S)._an_element_
Cached version of <function _an_element_from_iterator at ...>
sage: S._an_element_()
1
sage: S = FiniteEnumeratedSet([])
sage: S._an_element_()
Traceback (most recent call last):
...
EmptySetError

_repr_option(key)
    Metadata about the _repr_() output.
```

INPUT:

•key – string. A key for different metadata informations that can be inquired about.

Valid key arguments are:

- •' ascii_art': The _repr_() output is multi-line ascii art and each line must be printed starting at the same column, or the meaning is lost.
- •'element_ascii_art': same but for the output of the elements. Used in sage.misc.displayhook.
- •' element_is_atomic': the elements print atomically, that is, parenthesis are not required when printing out any of x y, x + y, x^y and x/y.

OUTPUT:

Boolean.

EXAMPLES:

```
sage: ZZ._repr_option('ascii_art')
False
sage: MatrixSpace(ZZ, 2)._repr_option('element_ascii_art')
True
```

_init_category_(category)

Initialize the category framework

Most parents initialize their category upon construction, and this is the recommended behavior. For example, this happens when the constructor calls Parent.__init__() directly or indirectly. However, some parents defer this for performance reasons. For example, sage.matrix.matrix_space.MatrixSpace does not.

EXAMPLES:

Hom (codomain, category=None)

Return the homspace Hom (self, codomain, category).

INPUT:

- •codomain a parent
- •category a category or None (default: None) If None, the meet of the category of self and codomain is used.

OUTPUT:

The homspace of all homomorphisms from self to codomain in the category category.

See Also:

```
Hom()
```

EXAMPLES:

```
sage: R.\langle x, y \rangle = PolynomialRing(QQ, 2)
sage: R.Hom(QQ)
```

Set of Homomorphisms from Multivariate Polynomial Ring in x, y over Rational Field to Ration

Homspaces are defined for very general Sage objects, even elements of familiar rings:

```
sage: n = 5; Hom(n,7)
Set of Morphisms from 5 to 7 in Category of elements of Integer Ring
sage: z=(2/3); Hom(z,8/1)
Set of Morphisms from 2/3 to 8 in Category of elements of Rational Field
```

This example illustrates the optional third argument:

```
sage: QQ.Hom(ZZ, Sets())
Set of Morphisms from Rational Field to Integer Ring in Category of sets
```

A parent may specify how to construct certain homsets by implementing a method $_$ Hom $_$ ' (codomain, category). See :func: '~sage.categories.homset.Hom() for details.

an_element()

Returns a (preferably typical) element of this parent.

This is used both for illustration and testing purposes. If the set self is empty, an_element() raises the exception EmptySetError.

This calls _an_element_() (which see), and caches the result. Parent are thus encouraged to override _an_element_().

```
sage: CDF.an_element()
1.0*I
sage: ZZ[['t']].an_element()
t
```

In case the set is empty, an EmptySetError is raised:

coerce(x)

Return x as an element of self, if and only if there is a canonical coercion from the parent of x to self.

EXAMPLES:

```
sage: QQ.coerce(ZZ(2))
2
sage: ZZ.coerce(QQ(2))
Traceback (most recent call last):
...
TypeError: no canonical coercion from Rational Field to Integer Ring
```

We make an exception for zero:

```
sage: V = GF(7)^7
sage: V.coerce(0)
(0, 0, 0, 0, 0, 0, 0)
```

coerce_embedding()

Return the embedding of self into some other parent, if such a parent exists.

This does not mean that there are no coercion maps from self into other fields, this is simply a specific morphism specified out of self and usually denotes a special relationship (e.g. sub-objects, choice of completion, etc.)

EXAMPLES:

```
sage: K.<a>=NumberField(x^3+x^2+1,embedding=1)
sage: K.coerce_embedding()
Generic morphism:
   From: Number Field in a with defining polynomial x^3 + x^2 + 1
   To: Real Lazy Field
   Defn: a -> -1.465571231876768?
sage: K.<a>=NumberField(x^3+x^2+1,embedding=CC.gen())
sage: K.coerce_embedding()
Generic morphism:
   From: Number Field in a with defining polynomial x^3 + x^2 + 1
   To: Complex Lazy Field
   Defn: a -> 0.2327856159383841? + 0.7925519925154479?*I
```

$coerce_map_from(S)$

Return a Map object to coerce from S to self if one exists, or None if no such coercion exists.

By trac ticket #12313, a special kind of weak key dictionary is used to store coercion and conversion maps, namely MonoDict. In that way, a memory leak was fixed that would occur in the following test:

```
sage: import gc
sage: _ = gc.collect()
sage: K = GF(1<<55,'t')
sage: for i in range(50):
....: a = K.random_element()
....: E = EllipticCurve(j=a)
....: b = K.has_coerce_map_from(E)
sage: _ = gc.collect()
sage: len([x for x in gc.get_objects() if isinstance(x,type(E))])
1</pre>
```

TESTS:

The following was fixed in trac ticket #12969:

```
sage: R = QQ['q,t'].fraction_field()
sage: Sym = sage.combinat.sf.sf.SymmetricFunctions(R)
sage: H = Sym.macdonald().H()
sage: P = Sym.macdonald().P()
sage: m = Sym.monomial()
sage: Ht = Sym.macdonald().Ht()
sage: phi = m.coerce_map_from(P)
```

construction()

Returns a pair (functor, parent) such that functor(parent) return self. If this ring does not have a functorial construction, return None.

EXAMPLES:

```
sage: QQ.construction()
(FractionField, Integer Ring)
sage: f, R = QQ['x'].construction()
sage: f
Poly[x]
sage: R
Rational Field
sage: f(R)
Univariate Polynomial Ring in x over Rational Field
```

$convert_map_from(S)$

This function returns a Map from S to self, which may or may not succeed on all inputs. If a coercion map from S to self exists, then the it will be returned. If a coercion from self to S exists, then it will attempt to return a section of that map.

Under the new coercion model, this is the fastest way to convert elements of S to elements of self (short of manually constructing the elements) and is used by $__call__()$.

```
sage: m = ZZ.convert_map_from(QQ)
sage: m
Generic map:
   From: Rational Field
   To: Integer Ring
sage: m(-35/7)
-5
sage: parent(m(-35/7))
Integer Ring
```

element class()

The (default) class for the elements of this parent

FIXME's and design issues:

- •If self.Element is "trivial enough", should we optimize it away with: self.element_class = dynamic_class("%s.element_class"%self.__class__.__name__, (category.element_class,), self.Element)
- •This should lookup for Element classes in all super classes

```
get_action (S, op=None, self_on_left=True, self_el=None, S_el=None)
```

Returns an action of self on S or S on self.

To provide additional actions, override _get_action_().

TESTS:

```
sage: M = QQ['y']^3
sage: M.get_action(ZZ['x']['y'])
Right scalar multiplication by Univariate Polynomial Ring in y over Univariate Polynomial Ris
sage: M.get_action(ZZ['x']) # should be None
```

$has_coerce_map_from(S)$

Return True if there is a natural map from S to self. Otherwise, return False.

EXAMPLES:

```
sage: RDF.has_coerce_map_from(QQ)
True
sage: RDF.has_coerce_map_from(QQ['x'])
False
sage: RDF['x'].has_coerce_map_from(QQ['x'])
True
sage: RDF['x,y'].has_coerce_map_from(QQ['x'])
True
```

hom (im_gens, codomain=None, check=None)

Return the unique homomorphism from self to codomain that sends self.gens() to the entries of im_gens. Raises a TypeError if there is no such homomorphism.

INPUT:

- •im_qens the images in the codomain of the generators of this object under the homomorphism
- •codomain the codomain of the homomorphism
- •check whether to verify that the images of generators extend to define a map (using only canonical coercions).

OUTPUT:

A homomorphism self -> codomain

Note: As a shortcut, one can also give an object X instead of im_gens, in which case return the (if it exists) natural map to X.

EXAMPLES:

Polynomial Ring: We first illustrate construction of a few homomorphisms involving a polynomial ring:

```
sage: R.<x> = PolynomialRing(ZZ)
sage: f = R.hom([5], QQ)
```

```
sage: f(x^2 - 19)
    sage: R.<x> = PolynomialRing(QQ)
    sage: f = R.hom([5], GF(7))
    Traceback (most recent call last):
    TypeError: images do not define a valid homomorphism
    sage: R.<x> = PolynomialRing(GF(7))
    sage: f = R.hom([3], GF(49,'a'))
    sage: f
    Ring morphism:
      From: Univariate Polynomial Ring in x over Finite Field of size 7
      To: Finite Field in a of size 7^2
      Defn: x \mid --> 3
    sage: f(x+6)
    sage: f(x^2+1)
    Natural morphism:
    sage: f = ZZ.hom(GF(5))
    sage: f(7)
    sage: f
    Ring Coercion morphism:
      From: Integer Ring
      To: Finite Field of size 5
    There might not be a natural morphism, in which case a TypeError is raised:
    sage: QQ.hom(ZZ)
    Traceback (most recent call last):
    TypeError: Natural coercion morphism from Rational Field to Integer Ring not defined.
is_atomic_repr()
    The old way to signal atomic string reps.
    True if the elements have atomic string representations, in the sense that if they print at s, then -s means
    the negative of s. For example, integers are atomic but polynomials are not.
    EXAMPLES:
    sage: Parent().is_atomic_repr()
    doctest:...: DeprecationWarning: Use _repr_option to return metadata about string rep
    See http://trac.sagemath.org/14040 for details.
    False
is_coercion_cached(domain)
is_conversion_cached(domain)
is_exact()
    Test whether the ring is exact.
```

Note: This defaults to true, so even if it does return True you have no guarantee (unless the ring has properly overloaded this).

OUTPUT:

Return True if elements of this ring are represented exactly, i.e., there is no precision loss when doing arithmetic.

EXAMPLES:

```
sage: QQ.is_exact()
True
sage: ZZ.is_exact()
True
sage: Qp(7).is_exact()
False
sage: Zp(7, type='capped-abs').is_exact()
False
```

register_action(action)

Update the coercion model to use action to act on self.

action should be of type sage.categories.action.Action.

EXAMPLES:

```
sage: import sage.categories.action
sage: import operator
sage: class SymmetricGroupAction(sage.categories.action.Action):
          "Act on a multivariate polynomial ring by permuting the generators."
. . . . :
          def __init__(self, G, M, is_left=True):
               sage.categories.action.Action.__init__(self, G, M, is_left, operator.mul)
. . . . :
. . . . :
          def _call_(self, g, a):
. . . . :
               if not self.is_left():
                   g, a = a, g
               D = \{ \}
               for k, v in a.dict().items():
. . . . :
                   nk = [0] *len(k)
. . . . :
                   for i in range(len(k)):
. . . . :
                       nk[g(i+1)-1] = k[i]
. . . . :
                   D[tuple(nk)] = v
. . . . :
              return a.parent()(D)
. . . . :
sage: R.\langle x, y, z \rangle = QQ['x, y, z']
sage: G = SymmetricGroup(3)
sage: act = SymmetricGroupAction(G, R)
sage: t = x + 2*y + 3*z
sage: act(G((1, 2)), t)
2*x + y + 3*z
sage: act(G((2, 3)), t)
x + 3*y + 2*z
sage: act(G((1, 2, 3)), t)
3*x + y + 2*z
```

This should fail, since we haven't registered the left action:

```
sage: G((1,2)) * t
Traceback (most recent call last):
...
TypeError: ...
```

Now let's make it work:

```
sage: R._unset_coercions_used()
sage: R.register_action(act)
sage: G((1, 2)) * t
2*x + y + 3*z
```

register_coercion(mor)

Update the coercion model to use $mor: P \rightarrow self$ to coerce from a parent P into self.

For safety, an error is raised if another coercion has already been registered or discovered between P and self.

EXAMPLES:

```
sage: K.<a> = ZZ['a']
sage: L.<b> = ZZ['b']
sage: L_into_K = L.hom([-a]) # non-trivial automorphism
sage: K.register_coercion(L_into_K)

sage: K(0) + b
-a
sage: a + b
0
sage: K(b) # check that convert calls coerce first; normally this is just a
-a

sage: L(0) + a in K # this goes through the coercion mechanism of K
True
sage: L(a) in L # this still goes through the convert mechanism of L
True

sage: K.register_coercion(L_into_K)
Traceback (most recent call last):
...
AssertionError: coercion from Univariate Polynomial Ring in b over Integer Ring to Univariate
```

$register_conversion(mor)$

Update the coercion model to use mor : $P \rightarrow \text{self}$ to convert from P into self.

EXAMPLES:

```
sage: K.<a> = ZZ['a']
sage: M.<c> = ZZ['c']
sage: M_into_K = M.hom([a]) # trivial automorphism
sage: K._unset_coercions_used()
sage: K.register_conversion(M_into_K)

sage: K(c)
a
sage: K(0) + c
Traceback (most recent call last):
...
TypeError: ...
```

register_embedding(embedding)

Add embedding to coercion model.

This method updates the coercion model to use embedding : self $\rightarrow P$ to embed self into the parent P.

There can only be one embedding registered; it can only be registered once; and it must be registered

before using this parent in the coercion model.

```
EXAMPLES:
```

```
sage: S3 = AlternatingGroup(3)
sage: G = SL(3, QQ)
sage: p = S3[2]; p.matrix()
[0 0 1]
[1 0 0]
[0 1 0]
```

In general one can't mix matrices and permutations:

```
sage: G(p)
Traceback (most recent call last):
...
TypeError: entries must be coercible to a list or integer
sage: phi = S3.hom(lambda p: G(p.matrix()), codomain = G)
sage: phi(p)
[0 0 1]
[1 0 0]
[0 1 0]
sage: S3._unset_coercions_used()
sage: S3.register_embedding(phi)
```

By trac ticket #14711, coerce maps should be copied when using outside of the coercion system:

```
sage: phi = copy(S3.coerce_embedding()); phi
Generic morphism:
  From: Alternating group of order 3!/2 as a permutation group
  To: Special Linear Group of degree 3 over Rational Field
sage: phi(p)
[0 0 1]
[1 0 0]
[0 1 0]
```

This does not work since matrix groups are still old-style parents (see trac ticket #14014):

```
sage: G(p) # todo: not implemented
```

Though one can have a permutation act on the rows of a matrix:

```
sage: G(1) * p
[0 0 1]
[1 0 0]
[0 1 0]
```

Some more advanced examples:

```
sage: x = QQ['x'].0
sage: t = abs(ZZ.random_element(10^6))
sage: K = NumberField(x^2 + 2*3*7*11, "a"+str(t))
sage: a = K.gen()
sage: K_into_MS = K.hom([a.matrix()])
sage: K._unset_coercions_used()
sage: K.register_embedding(K_into_MS)

sage: L = NumberField(x^2 + 2*3*7*11*19*31, "b"+str(abs(ZZ.random_element(10^6))))
sage: b = L.gen()
sage: L_into_MS = L.hom([b.matrix()])
sage: L._unset_coercions_used()
sage: L.register_embedding(L_into_MS)
```

```
sage: K.coerce_embedding()(a)
        [ 0 1]
        [-462 0]
        sage: L.coerce_embedding()(b)
        [ 0 1]
        [-272118]
                       01
        sage: a.matrix() * b
        [-272118 0]
               0
                    -462]
        sage: a * b.matrix()
        [-272118
                      0 ]
             0 -462]
        [
sage.structure.parent.Set_PythonType(theType)
    Return the (unique) Parent that represents the set of Python objects of a specified type.
    EXAMPLES:
      sage: from sage.structure.parent import Set_PythonType
      sage: Set_PythonType(list)
      Set of Python objects of type 'list'
      sage: Set_PythonType(list) is Set_PythonType(list)
      sage: S = Set_PythonType(tuple)
      sage: S([1,2,3])
      (1, 2, 3)
    S is a parent which models the set of all lists:
      sage: S.category()
      Category of sets
    EXAMPLES:
    sage: R = sage.structure.parent.Set_PythonType(int)
    sage: S = sage.structure.parent.Set_PythonType(float)
    sage: Hom(R, S)
    Set of Morphisms from Set of Python objects of type 'int' to Set of Python objects of type 'float
class sage.structure.parent.Set_PythonType_class
    Bases: sage.structure.parent.Set_generic
    EXAMPLES:
    sage: S = sage.structure.parent.Set_PythonType(float)
    sage: S.category()
    Category of sets
    cardinality()
        EXAMPLES:
        sage: S = sage.structure.parent.Set_PythonType(bool)
        sage: S.cardinality()
        sage: S = sage.structure.parent.Set_PythonType(int)
        sage: S.cardinality()
        4294967296
                                           # 32-bit
        18446744073709551616
                                           # 64-bit
        sage: S = sage.structure.parent.Set_PythonType(float)
```

sage: S.cardinality()

```
18437736874454810627
         sage: S = sage.structure.parent.Set_PythonType(long)
         sage: S.cardinality()
         +Infinity
    object()
         EXAMPLES:
         sage: S = sage.structure.parent.Set_PythonType(tuple)
         sage: S.object()
         <type 'tuple'>
class sage.structure.parent.Set_generic
    Bases: sage.structure.parent.Parent
    Abstract base class for sets.
    TESTS:
    sage: Set(QQ).category()
    Category of sets
    object()
sage.structure.parent.is_Parent(x)
    Return True if x is a parent object, i.e., derives from sage.structure.parent.Parent and False otherwise.
    EXAMPLES:
    sage: from sage.structure.parent import is_Parent
    sage: is_Parent(2/3)
    False
    sage: is_Parent(ZZ)
    sage: is_Parent(Primes())
    True
sage.structure.parent.normalize_names (ngens, names)
    sage: sage.structure.parent.normalize_names(5, 'x')
     ('x0', 'x1', 'x2', 'x3', 'x4')
    sage: sage.structure.parent.normalize_names(2, ['x','y'])
     ('x', 'y')
```
